# LAX FUNCTORIALITIES OF THE COMMA CONSTRUCTION FOR $\omega$ -CATEGORIES

*by*

Dimitri Ara & Léonard Guetta

---

**Abstract.** — Motivated by the Grothendieck construction, we study the functorialities of the comma construction for strict  $\omega$ -categories. To state the most general functorialities, we use the language of Gray  $\omega$ -categories, that is, categories enriched in the category of strict  $\omega$ -categories endowed with the oplax Gray tensor product. Our main result is that the comma construction of strict  $\omega$ -categories defines a Gray  $\omega$ -functor, that is, a morphism of Gray  $\omega$ -categories. To make sense of this statement, we prove that slices of Gray  $\omega$ -categories exist. Coming back to the Grothendieck construction, we propose a definition in terms of the comma construction and, as a consequence, we get that the Grothendieck construction of strict  $\omega$ -categories defines a Gray  $\omega$ -functor. Finally, as a by-product, we get a notion of Grothendieck construction for Gray  $\omega$ -functors, which we plan to investigate in future work.

## Introduction

### The starting point: the Grothendieck construction

The classical Grothendieck construction defines, for every small category  $I$ , a functor

$$\int_I: \underline{\mathbf{Hom}}(I^\circ, \mathbf{Cat}) \rightarrow \mathbf{Cat}$$

that sends a functor  $F: I^\circ \rightarrow \mathbf{Cat}$ , where  $I^\circ$  denotes the opposite category of  $I$  and  $\mathbf{Cat}$  the category of small categories, to the so-called *Grothendieck construction*  $\int_I F$  of  $F$ . Here  $\underline{\mathbf{Hom}}$  denotes the cartesian internal Hom of  $\mathbf{Cat}$ , whose morphisms are strict natural transformations. But the functorialities of the Grothendieck construction are more general. First, if  $F, G: I^\circ \rightarrow \mathbf{Cat}$  are two such functors and  $\alpha: F \Rightarrow G$  is an *oplax* transformation (that is, roughly speaking, a transformation where the naturality squares only commute up to a non-invertible 2-cell), then one can still integrate  $\alpha$  to

**2020 Mathematics Subject Classification.** — 18A25, 18D20, 18N20, 18N30.

**Keywords.** —  $\omega$ -categories, comma  $\omega$ -categories, Gray  $\omega$ -categories, Gray  $\omega$ -functors, Grothendieck construction, slice Gray  $\omega$ -categories, strict  $\omega$ -categories.

obtain a functor  $\int_I \alpha: \int_I F \rightarrow \int_I G$ . Second, the construction is also functorial in  $I$ . Combining these, we get a functoriality

$$\begin{array}{ccc}
 I^\circ & \xrightarrow{u^\circ} & J^\circ \\
 \downarrow F & \searrow \alpha & \downarrow G \\
 & \text{Cat} & 
 \end{array}
 \quad \mapsto \quad
 \int_I F \xrightarrow{\int(u, \alpha)} \int_J G \quad ,$$

where  $\alpha$  is an oplax transformation.

The purpose of this paper is to study higher generalizations of these functorialities in the setting of strict  $\omega$ -categories. Our original motivation was to investigate the homotopical properties of the Grothendieck construction for strict  $\omega$ -categories, and particularly the generalization of a theorem by Thomason [8], which will be addressed in a separate paper [2].

### From the Grothendieck construction to comma $\omega$ -categories

Let  $\omega\text{-Cat}$  denote the category of strict  $\omega$ -categories and strict  $\omega$ -functors. Using its cartesian internal  $\text{Hom}$ , this category can be promoted to a strict  $\omega$ -category  $\omega\text{-Cat}_{\text{cart}}$ , whose 2-cells are strict transformations and whose higher cells are strict higher transformations. If now  $F: I^\circ \rightarrow \omega\text{-Cat}_{\text{cart}}$  is a strict  $\omega$ -functor, where  $I$  is a strict  $\omega$ -category and  $I^\circ$  denotes the dual  $\omega$ -category obtained by reversing the orientation of all the cells of  $I$ , then a Grothendieck construction  $\int_I F$  was defined by Warren in his work on the model of strict  $\omega$ -groupoids for dependent type theory [9].

However, the definition given by Warren is unsatisfactory as it relies on explicit and complicated formulas. We propose to *define* the Grothendieck construction of  $F: I^\circ \rightarrow \omega\text{-Cat}_{\text{cart}}$  as the universal  $\omega$ -category  $\int_I F$  endowed with a 2-square

$$\begin{array}{ccc}
 & (\int_I F)^\circ & \\
 \swarrow & & \searrow \\
 D_0 & \xrightarrow{\gamma} & I^\circ \\
 \searrow c_{D_0} & & \swarrow F \\
 & \omega\text{-Cat}_{\text{cart}} & 
 \end{array}
 \quad ,$$

where  $D_0$  denotes the terminal  $\omega$ -category,  $c_{D_0}$  the constant  $\omega$ -functor of value  $D_0$  and  $\gamma$  an oplax transformation. This type of universal 2-squares was already studied by the first-named author and Maltiniotis [3] and is a straightforward generalization of the classical comma construction of two functors  $f: A \rightarrow C$  and  $g: B \rightarrow C$ , usually denoted by  $f \downarrow g$ . More precisely, we have

$$\int_I F = (c_{D_0} \downarrow F)^\circ ,$$

where  $\downarrow$  denotes the *oplax* comma construction. Although these definitions are abstract, explicit formulas can be extracted, and we recover Warren’s formulas from this abstract point of view.

We are thus led to consider the following more general case. Let  $A, B$  and  $C$  be three strict  $\omega$ -categories, and let  $f: A \rightarrow C$  and  $g: B \rightarrow C$  be two strict  $\omega$ -functors. We can form the (oplax) comma  $\omega$ -category  $A \downarrow_C B$ , that is, the universal strict  $\omega$ -category equipped with a 2-square

where  $\gamma$  is an oplax transformation. Our goal is now to study the functorialities of  $A \downarrow_C B$  in  $g: B \rightarrow C$ , with  $f: A \rightarrow C$  fixed, and symmetrically, for which the functorialities of the Grothendieck construction are a particular case. The universal property of the comma construction immediately gives a functoriality

where the 2-cell represents an oplax transformation. Working a bit harder, the first-named author and Maltsiniotis got a functoriality

where the 2-cells represent oplax transformations and the 3-cell represents an oplax 2-transformation (also known as an oplax modification), and proved that the comma construction defines a sesquifunctor (see [3, Theorem B.2.6]). And now comes the question: what is the general functoriality statement?

**The need for Gray  $\omega$ -categories and their slices**

The answer to this question uses the language of Gray  $\omega$ -categories, which the first-named author introduced with Maltsiniotis in their work on the join construction and the slices [4]. Indeed, the diagrams above involving 0-cells, 1-cells, 2-cells and 3-cells actually live in  $\omega\text{-Cat}_{\text{oplax}}$ , in which 0-cells are strict  $\omega$ -categories, 1-cells are strict

$\omega$ -functors, 2-cells are oplax transformations, 3-cells are oplax 2-transformations, and so on. But  $\omega\text{-Cat}_{\text{oplax}}$  is not an  $\omega$ -category, *not even weak!* Indeed, if

$$A \begin{array}{c} \xrightarrow{\quad} \\ \Downarrow \alpha \\ \xrightarrow{\quad} \end{array} B \begin{array}{c} \xrightarrow{\quad} \\ \Downarrow \beta \\ \xrightarrow{\quad} \end{array} C$$

are two oplax transformations, then there are a priori two ways of composing them:

$$(t(\beta) *_{0} \alpha) *_{1} (\beta *_{0} s(\alpha)) \quad \text{and} \quad (\beta *_{0} t(\alpha)) *_{1} (s(\beta) *_{0} \alpha),$$

where  $s$  and  $t$  denote the source and the target. In general, these two oplax transformations are different! In other words,  $\omega\text{-Cat}_{\text{oplax}}$  does not satisfy the exchange rule. What is true is that there is a *non-invertible* canonical oplax 2-transformation

$$(\beta *_{0} t(\alpha)) *_{1} (s(\beta) *_{0} \alpha) \Longrightarrow (t(\beta) *_{0} \alpha) *_{1} (\beta *_{0} s(\alpha)),$$

which can be pictured as

$$\left\{ \begin{array}{c} A \begin{array}{c} \xrightarrow{\quad} \\ \Downarrow \alpha \\ \xrightarrow{\quad} \end{array} B \longrightarrow C \\ \quad \quad \quad *_{1} \\ A \longrightarrow B \begin{array}{c} \xrightarrow{\quad} \\ \Downarrow \beta \\ \xrightarrow{\quad} \end{array} C \end{array} \right\} \cong \left\{ \begin{array}{c} A \longrightarrow B \begin{array}{c} \xrightarrow{\quad} \\ \Downarrow \beta \\ \xrightarrow{\quad} \end{array} C \\ \quad \quad \quad *_{1} \\ A \begin{array}{c} \xrightarrow{\quad} \\ \Downarrow \alpha \\ \xrightarrow{\quad} \end{array} B \longrightarrow C \end{array} \right\}.$$

This means that  $\omega\text{-Cat}_{\text{oplax}}$  is some kind of oplax  $\omega$ -category. Formally,  $\omega\text{-Cat}_{\text{oplax}}$  is what we call a *Gray  $\omega$ -category*, that is, a category enriched in  $\omega\text{-Cat}$  endowed with the oplax Gray tensor product. Morphisms of Gray  $\omega$ -categories are called *Gray  $\omega$ -functors*.

Let us come back to the comma construction. It seems reasonable to expect that if the correspondence

$$A \downarrow_C - : (B, B \rightarrow C) \mapsto A \downarrow_C B$$

extends to a Gray  $\omega$ -functor, then its target should be  $\omega\text{-Cat}_{\text{oplax}}$ . But what would be the source Gray  $\omega$ -category? Or, in other words, in which Gray  $\omega$ -category do the triangles and cones we drew earlier are 1-cells and 2-cells? Obviously, in some kind of slice Gray  $\omega$ -category  $\omega\text{-Cat}_{\text{oplax}}/C$  of the Gray  $\omega$ -category  $\omega\text{-Cat}_{\text{oplax}}$  above the strict  $\omega$ -category  $C$  (which is an object of  $\omega\text{-Cat}_{\text{oplax}}$ ). We prove that slice Gray  $\omega$ -categories exist, in full generality:

**Theorem.** — *Let  $\mathbb{C}$  be a Gray  $\omega$ -category and let  $c$  be an object of  $\mathbb{C}$ . Then there is a (natural) Gray  $\omega$ -category  $\mathbb{C}/_c$  of objects of  $\mathbb{C}$  over  $c$ .*

In the case that  $\mathbb{C}$  is a *strict*  $\omega$ -category (which we can consider as a Gray  $\omega$ -category where the exchange rule is an equality), we recover the usual notion of slices of strict  $\omega$ -categories (see for instance [4, Chapter 9]). Note that the existence of slices of Gray  $\omega$ -categories was first conjectured in [4, Appendix C].

**Our Gray-functoriality results**

Using slices of Gray  $\omega$ -categories, we can finally express the desired functoriality of the construction  $A \downarrow_C B$ , actually both in  $A$  and  $B$  simultaneously, which is the main result of our paper:

**Theorem.** — *The oplax comma construction  $-\downarrow_C-$  defines a Gray  $\omega$ -functor*

$$-\downarrow_C- : \omega\text{-Cat}_{\text{oplax}}/C \times \omega\text{-Cat}_{\text{oplax}}/C \xrightarrow{\text{to}} \omega\text{-Cat}_{\text{oplax}},$$

where the decoration “to” indicates a duality by which the slice has to be conjugated.

This theorem gives the full functorialities of the comma construction. In particular, in low dimensions, we recover the sesquifunctor of [3, Theorem B.2.6] and the mapping

where 2-cells represent oplax transformations and the 3-cell represents an oplax 2-transformation. Concretely, our theorem asserts that this mapping generalizes to cones of any dimension and higher oplax transformations, and moreover that these mappings are compatible with all the compositions of Gray slices.

This theorem is an instance of an idea we would like to put forward: *every functorial construction on  $\omega$ -categories should be promoted to a Gray  $\omega$ -functor.*

Note that, as the duality appearing in the statement of the theorem shows, dualities of strict and Gray  $\omega$ -categories play an important and subtle role in this paper, and we study them with great care.

As a direct corollary of the theorem, we get:

**Corollary.** — *Let  $A$  and  $B$  be two strict  $\omega$ -categories. The oplax comma construction restricts to a Gray  $\omega$ -functor*

$$-\downarrow_C- : \underline{\text{Hom}}_{\text{oplax}}(A, C)^{\circ} \times \underline{\text{Hom}}_{\text{oplax}}(B, C)^{\text{to}} \rightarrow \omega\text{-Cat}_{\text{oplax}},$$

where  $\underline{\text{Hom}}_{\text{oplax}}(X, Y)$  denotes the strict  $\omega$ -category of strict  $\omega$ -functors from  $X$  to  $Y$ , oplax transformations and higher oplax transformations between them.

We also study the functorialities of the oplax comma construction restricted to higher *strict* transformations. The  $\omega$ -category  $\omega\text{-Cat}_{\text{cart}}$  can be seen as sub-Gray  $\omega$ -category of  $\omega\text{-Cat}_{\text{oplax}}$  by considering higher strict transformations as particular higher oplax transformations. A priori, we get by restriction a Gray  $\omega$ -functor

$$-\downarrow_C- : \omega\text{-Cat}_{\text{cart}}/C \times \omega\text{-Cat}_{\text{cart}}/C \xrightarrow{\text{to}} \omega\text{-Cat}_{\text{oplax}},$$

but we prove that it actually lands into  $\omega\text{-Cat}_{\text{cart}}$ :

**Proposition.** — *The oplax comma construction restricts to a strict  $\omega$ -functor*

$$-\downarrow_C -: \omega\text{-Cat}_{\text{cart}}/C \times \omega\text{-Cat}_{\text{cart}}^{\text{to}}/C \rightarrow \omega\text{-Cat}_{\text{cart}} .$$

Finally, we apply all these results to the particular case of the Grothendieck construction. For that, notice that the  $\omega$ -category  $\omega\text{-Cat}_{\text{cart}}$  is an object of  $\omega\text{-CAT}_{\text{oplax}}$  the (very large) Gray strict  $\omega$ -category of possibly large strict  $\omega$ -categories, strict  $\omega$ -functors and lax (higher) transformations between them. We get:

**Corollary.** — *The Grothendieck construction defines a Gray  $\omega$ -functor*

$$\int : (\omega\text{-CAT}_{\text{oplax}} / \{\omega\text{-Cat}_{\text{cart}}\})^{\text{to}} \rightarrow \omega\text{-CAT}_{\text{oplax}} \\ (F : I^\circ \rightarrow \omega\text{-Cat}_{\text{cart}}) \mapsto \int_I F \quad ,$$

$\omega\text{-Cat}_{\text{oplax}} / \{\omega\text{-Cat}_{\text{cart}}\}^{\text{to}}$  being the full sub-Gray  $\omega$ -category of  $\omega\text{-CAT}_{\text{oplax}} / \{\omega\text{-Cat}_{\text{cart}}\}^{\text{to}}$  spanned by those  $\omega$ -functors  $F : I^\circ \rightarrow \omega\text{-Cat}_{\text{cart}}$ , where  $I$  is a small  $\omega$ -category.

In particular, if we fix a strict  $\omega$ -category  $I$ , the above Gray  $\omega$ -functor restricts to a Gray  $\omega$ -functor

$$\int_I : \underline{\text{Hom}}_{\text{oplax}}(I^\circ, \omega\text{-Cat}_{\text{cart}}) \rightarrow \omega\text{-CAT}_{\text{oplax}} ,$$

as well as to a strict  $\omega$ -functor

$$\int_I : \underline{\text{Hom}}(I^\circ, \omega\text{-Cat}_{\text{cart}}) \rightarrow \omega\text{-Cat}_{\text{cart}} ,$$

where  $\underline{\text{Hom}}$  is the cartesian internal Hom of  $\omega\text{-CAT}$ , the (very large) category of possibly large strict  $\omega$ -categories.

Note that functorialities of the Grothendieck construction in the setting of *weak*  $\omega$ -categories have been studied recently by Loubaton [7]. However, our work is not a particular case of his as, first, Loubaton only deals with the case of a fixed base (weak)  $\omega$ -category  $I$  and, second, he only considers a (weak) sub- $\omega$ -category of  $\underline{\text{Hom}}_{\text{oplax}}(I^\circ, \omega\text{-Cat}_{\text{cart}})$ , containing oplax transformations but not general oplax  $n$ -transformations for  $n > 1$ . In other words, the generalization of our work to weak  $\omega$ -categories would give more general functorialities than the ones studied by Loubaton.

### A side remark on cylinders in Gray $\omega$ -categories

It seems important to bring the reader's attention to the fact that there is a *tour de force* behind the definition of slice Gray  $\omega$ -category  $\mathbb{C}/c$ . Intuitively, to define such Gray  $\omega$ -categories, one must make sense in an arbitrary Gray  $\omega$ -category of pasting

diagrams shaped like (higher) cones

as well as defining compositions between those. For example, defining the whiskering operation of a 2-cell with a 1-cell in slice Gray  $\omega$ -categories amounts to define a “total composite” of the following pasting diagram:

In the case of *strict*  $\omega$ -categories, the cone-shaped pasting diagrams are considered as degenerate cases of cylinder-shaped pasting diagrams

and the compositions between cone-shaped diagrams are induced by the ones at the level of cylinders. *However*, for Gray  $\omega$ -categories, it is not possible to define all the cylinder compositions that would be required to then deduce the ones for cones as a particular case. For example, we let the reader convince themselves that it is not possible to make sense of the total composite of the following pasting diagram in a Gray  $\omega$ -category:

Hence, the fact that we can nonetheless define cone-shaped diagrams and their compositions within a Gray  $\omega$ -category suggests the existence of an interesting but not yet fully understood theory of pasting diagrams in Gray  $\omega$ -categories.

### Towards a Grothendieck construction for Gray $\omega$ -functors

Let us end this introduction with a noticeable by-product result that we obtain in this paper. As noted before, the Grothendieck construction of an  $\omega$ -functor  $F: I^\circ \rightarrow \omega\text{-Cat}$  can be defined as (the dual of) a comma  $\omega$ -category. In fact, this comma  $\omega$ -category is (the dual of) a relative slice, meaning it is obtained by pulling back a slice  $\omega$ -category as follows:

$$\begin{array}{ccc} (\int_I F)^\circ & \longrightarrow & D_0 \backslash \omega\text{-Cat} \\ \downarrow & \lrcorner & \downarrow \\ I^\circ & \xrightarrow{F} & \omega\text{-Cat} \end{array} .$$

The advantage of this description is that it can be adapted straightforwardly in the context of Gray  $\omega$ -categories, up to some subtleties on dualities. If  $\mathbb{C}$  is a (small) Gray  $\omega$ -category, then its dual obtained by reversing the orientation of all the cells is not a Gray  $\omega$ -category but what we call a *skew* Gray  $\omega$ -category. By that, we mean a category enriched in  $\omega\text{-Cat}$ , endowed with the oplax Gray tensor product, but with the composition morphisms of type

$$\underline{\text{Hom}}(X, Y) \otimes \underline{\text{Hom}}(Y, Z) \rightarrow \underline{\text{Hom}}(X, Z)$$

(as opposed to  $\underline{\text{Hom}}(Y, Z) \otimes \underline{\text{Hom}}(X, Y) \rightarrow \underline{\text{Hom}}(X, Z)$ , which is a different notion as the oplax Gray tensor product is not symmetrical and not even braided). As an example of a skew Gray  $\omega$ -category, we have  $\omega\text{-Cat}_{\text{lax}}$ , whose 0-cells are strict  $\omega$ -categories, 1-cells are strict  $\omega$ -functors and higher cells are higher *lax* transformations. Now, given a (small) Gray  $\omega$ -category  $\mathbb{C}$  and  $F: \mathbb{C}^\circ \rightarrow \omega\text{-Cat}_{\text{lax}}$  a skew Gray  $\omega$ -functor, we define the (dual of the) Grothendieck construction  $\int_{\mathbb{C}} F$  of  $F$  as the following pullback:

$$\begin{array}{ccc} (\int_{\mathbb{C}} F)^\circ & \longrightarrow & D_0 \backslash \omega\text{-Cat}_{\text{lax}} \\ \downarrow & \lrcorner & \downarrow \\ \mathbb{C}^\circ & \xrightarrow{F} & \omega\text{-Cat}_{\text{lax}} \end{array} .$$

Note that  $\int_{\mathbb{C}} F$  is indeed a Gray  $\omega$ -category (and not a skew Gray  $\omega$ -category). As already said, the dualities for strict and Gray  $\omega$ -categories are subtle and we study them thoroughly in this paper.

We plan to work more extensively on this Grothendieck construction in the context of Gray  $\omega$ -categories in future work.

### Acknowledgments

The authors would like to thank Andrea Gagna, Félix Loubaton, Maxime Lucas and Georges Maltsiniotis for helpful conversations on the subject of this paper.

### 1. Preliminaries on enriched categories

We begin with some preliminaries on categories enriched in a monoidal category. Our case of interest is the category of strict  $\omega$ -categories endowed with the Gray tensor product, which will be introduced in the next section. This tensor product is *not* symmetric (and not even braided).

**1.1.** — Let  $\mathcal{V} = (\mathcal{V}, \otimes, I)$  be a monoidal category. Since we do not assume  $\mathcal{V}$  to be symmetric, we need to distinguish between the notion of a  $\mathcal{V}$ -category (or a category enriched in  $\mathcal{V}$ ) and that of a *skew*  $\mathcal{V}$ -category.

A  $\mathcal{V}$ -category  $\mathcal{A}$  is given by

- a set of *objects*  $\text{Ob}(\mathcal{A})$ ,
- for every objects  $X$  and  $Y$  of  $\mathcal{A}$ , an *object of morphisms*  $\underline{\text{Hom}}_{\mathcal{A}}(X, Y)$  in  $\mathcal{V}$ ,
- for every objects  $X, Y$  and  $Z$  of  $\mathcal{A}$ , a *composition morphism*

$$\circ: \underline{\text{Hom}}_{\mathcal{A}}(Y, Z) \otimes \underline{\text{Hom}}_{\mathcal{A}}(X, Y) \rightarrow \underline{\text{Hom}}_{\mathcal{A}}(X, Z)$$

in  $\mathcal{V}$ ,

- for every object  $X$  of  $\mathcal{A}$ , an *identity morphism*

$$1_X: I \rightarrow \underline{\text{Hom}}_{\mathcal{A}}(X, X)$$

in  $\mathcal{V}$ ,

satisfying well-known axioms.

The notion of a *skew*  $\mathcal{V}$ -category is obtained likewise but with composition morphisms of type

$$\circ: \underline{\text{Hom}}_{\mathcal{A}}(X, Y) \otimes \underline{\text{Hom}}_{\mathcal{A}}(Y, Z) \rightarrow \underline{\text{Hom}}_{\mathcal{A}}(X, Z).$$

More formally, a skew  $\mathcal{V}$ -category is a  $\bar{\mathcal{V}}$ -category, where  $\bar{\mathcal{V}}$  denotes the monoidal category  $(\mathcal{V}, \bar{\otimes}, I)$ , the monoidal product  $\bar{\otimes}$  being defined by  $X \bar{\otimes} Y = Y \otimes X$ .

We denote by  $\mathcal{V}\text{-Cat}$  the (large) 2-category whose objects are  $\mathcal{V}$ -categories, whose morphisms are  $\mathcal{V}$ -functors and whose 2-morphisms are  $\mathcal{V}$ -natural transformations. Consequently, the 2-category  $\bar{\mathcal{V}}\text{-Cat}$  is the 2-category of skew  $\mathcal{V}$ -categories. Its morphisms are called *skew  $\mathcal{V}$ -functors* and its 2-morphisms *skew  $\mathcal{V}$ -natural transformations*.

**1.2.** — Let  $\mathcal{V}$  be a monoidal category. Given a  $\mathcal{V}$ -category  $\mathcal{A}$ , we define its *transpose* to be the obvious *skew*  $\mathcal{V}$ -category  $\mathcal{A}^t$  which has the same set of objects as  $\mathcal{A}$  and  $\text{Hom}$  defined by

$$\underline{\text{Hom}}_{\mathcal{A}^t}(X, Y) = \underline{\text{Hom}}_{\mathcal{A}}(Y, X).$$

Similarly, the *transpose* of a skew  $\mathcal{V}$ -category is the  $\mathcal{V}$ -category obtained in the analogous way.

The correspondence which sends a  $\mathcal{V}$ -category to its transpose canonically extends to a 2-functor

$$\begin{aligned} (-)^t: (\mathcal{V}\text{-Cat})^{\text{co}} &\rightarrow \overline{\mathcal{V}}\text{-Cat} \\ \mathcal{A} &\mapsto \mathcal{A}^t, \end{aligned}$$

where the decoration “co” indicates that the orientation of the 2-cells of  $\mathcal{V}\text{-Cat}$  is reversed.

**1.3.** — Let  $\mathcal{V}$  be a monoidal category. Recall that if  $\mathcal{V}$  admits limits indexed by a given category, then so does  $\mathcal{V}\text{-Cat}$ . In particular, let us describe the case of binary products explicitly. If  $\mathcal{A}$  and  $\mathcal{B}$  are two  $\mathcal{V}$ -categories, their product  $\mathcal{V}$ -category  $\mathcal{A} \times \mathcal{B}$  can be described in the following way:

- $\text{Ob}(\mathcal{A} \times \mathcal{B}) = \text{Ob}(\mathcal{A}) \times \text{Ob}(\mathcal{B})$ ,
- if  $X, X'$  are objects of  $\mathcal{A}$  and  $Y, Y'$  are objects of  $\mathcal{B}$ , then

$$\underline{\text{Hom}}_{\mathcal{A} \times \mathcal{B}}((X, Y), (X', Y')) = \underline{\text{Hom}}_{\mathcal{A}}(X, X') \times \underline{\text{Hom}}_{\mathcal{B}}(Y, Y'),$$

- if  $X, X', X''$  are objects of  $\mathcal{A}$  and  $Y, Y', Y''$  are objects of  $\mathcal{B}$ , the composition of  $\mathcal{A} \times \mathcal{B}$  is given by

$$\begin{aligned} &(\underline{\text{Hom}}_{\mathcal{A}}(X', X'') \times \underline{\text{Hom}}_{\mathcal{B}}(Y', Y'')) \otimes (\underline{\text{Hom}}_{\mathcal{A}}(X, X') \times \underline{\text{Hom}}_{\mathcal{B}}(Y, Y')) \\ &\quad \downarrow (p_1 \otimes p_1, p_2 \otimes p_2) \\ &(\underline{\text{Hom}}_{\mathcal{A}}(X', X'') \otimes \underline{\text{Hom}}_{\mathcal{A}}(X, X')) \times (\underline{\text{Hom}}_{\mathcal{B}}(Y', Y'') \otimes \underline{\text{Hom}}_{\mathcal{B}}(Y, Y')) \\ &\quad \downarrow \circ \times \circ \\ &\underline{\text{Hom}}_{\mathcal{A}}(X, X'') \times \underline{\text{Hom}}_{\mathcal{B}}(Y, Y'') \quad , \end{aligned}$$

where  $p_1$  and  $p_2$  denote the first and second projections of the cartesian product,

- if  $X$  is an object of  $\mathcal{A}$  and  $Y$  is an object of  $\mathcal{B}$ , the identity morphism of  $(X, Y)$  is

$$I \xrightarrow{(1_X, 1_Y)} \underline{\text{Hom}}_{\mathcal{A}}(X, X) \times \underline{\text{Hom}}_{\mathcal{B}}(Y, Y).$$

**1.4.** — Recall that if  $F: \mathcal{V} \rightarrow \mathcal{V}'$  is a lax monoidal functor between monoidal categories, then  $F$  induces a 2-functor

$$F_*: \mathcal{V}\text{-Cat} \rightarrow \mathcal{V}'\text{-Cat}$$

sending a  $\mathcal{V}$ -category  $\mathcal{A}$  to the obvious  $\mathcal{V}$ -category  $F_*(\mathcal{A})$  with the same set of objects as  $\mathcal{A}$  and

$$\underline{\text{Hom}}_{F_*(\mathcal{A})}(X, Y) = F(\underline{\text{Hom}}_{\mathcal{A}}(X, Y)).$$

We call *monoidal functor* a lax monoidal functor whose structural natural transformations are isomorphisms. We say that a functor  $F: \mathcal{V} \rightarrow \mathcal{V}'$  between two monoidal categories is *anti-monoidal* if it is monoidal considered as a functor  $F: \overline{\mathcal{V}} \rightarrow \mathcal{V}'$ , with the notation of 1.1.

**1.5.** — We say that a monoidal category  $\mathcal{V}$  is *closed on the right* if, for every object  $Y$  of  $\mathcal{V}$ , the functor  $- \otimes Y$  admits a right adjoint, then denoted by  $\underline{\mathbf{Hom}}_r(Y, -)$ . In this case, for  $X, Y$  and  $Z$  three objects of  $\mathcal{V}$ , we have a natural isomorphism

$$\mathbf{Hom}_{\mathcal{V}}(X \otimes Y, Z) \simeq \mathbf{Hom}_{\mathcal{V}}(X, \underline{\mathbf{Hom}}_r(Y, Z)).$$

If  $\mathcal{V}$  is closed on the right, there is an obvious  $\mathcal{V}$ -category, denoted by  $\mathcal{V}_r$ , whose objects are the same as those of  $\mathcal{V}$  and whose  $\mathbf{Hom}$  are given by  $\underline{\mathbf{Hom}}_r(X, Y)$ .

Dually we say that  $\mathcal{V}$  is *closed on the left* if, for every object  $X$  of  $\mathcal{V}$ , the functor  $X \otimes -$  admits a right adjoint, denoted by  $\underline{\mathbf{Hom}}_l(X, -)$ . We then have a natural isomorphism

$$\mathbf{Hom}_{\mathcal{V}}(X \otimes Y, Z) \simeq \mathbf{Hom}_{\mathcal{V}}(Y, \underline{\mathbf{Hom}}_l(X, Z)).$$

If  $\mathcal{V}$  is closed on the left, there is an obvious skew  $\mathcal{V}$ -category, denoted by  $\mathcal{V}_l$ , whose objects are the same as those of  $\mathcal{V}$  and whose  $\mathbf{Hom}$  are given by  $\underline{\mathbf{Hom}}_l(X, Y)$ .

We say that  $\mathcal{V}$  is *biclosed* if it is closed both on the left and on the right. In this case, we have a canonical isomorphism

$$\underline{\mathbf{Hom}}_l(X, \underline{\mathbf{Hom}}_r(Y, Z)) \simeq \underline{\mathbf{Hom}}_r(Y, \underline{\mathbf{Hom}}_l(X, Z)),$$

natural in  $X, Y$  and  $Z$  in  $\mathcal{V}$ .

**1.6.** — Let  $\mathcal{V}$  be a monoidal category closed on the right. Suppose that  $\mathcal{V}$  admits binary products. Then the binary product defines a  $\mathcal{V}$ -functor

$$\times : \mathcal{V}_r \times \mathcal{V}_r \rightarrow \mathcal{V}_r.$$

This  $\mathcal{V}$ -functor is given on objects by

$$(X, Y) \mapsto X \times Y,$$

and, if  $X, X', Y, Y'$  are four objects of  $\mathcal{V}$ , on  $\underline{\mathbf{Hom}}$  by the morphism

$$\underline{\mathbf{Hom}}_r(X, X') \times \underline{\mathbf{Hom}}_r(Y, Y') \rightarrow \underline{\mathbf{Hom}}_r(X \times Y, X' \times Y')$$

obtained by adjunction from the composite

$$\begin{array}{c} (\underline{\mathbf{Hom}}_r(X, X') \times \underline{\mathbf{Hom}}_r(Y, Y')) \otimes (X \times Y) \\ \downarrow (p_1 \otimes p_1, p_2 \otimes p_2) \\ (\underline{\mathbf{Hom}}_r(X, X') \otimes X) \times (\underline{\mathbf{Hom}}_r(Y, Y') \otimes Y) \xrightarrow{\text{ev} \times \text{ev}} X' \times Y', \end{array}$$

where  $p_1$  and  $p_2$  denote the two projections of the binary product, and  $\text{ev}$  the evaluation morphism of the right internal  $\mathbf{Hom}$ .

Similarly, if  $\mathcal{V}$  is closed on the left, we have a canonical skew  $\mathcal{V}$ -functor

$$\times : \mathcal{V}_l \times \mathcal{V}_l \rightarrow \mathcal{V}_l.$$

**1.7.** — Suppose now that  $\mathcal{V}$  is a biclosed monoidal category and let  $\mathcal{A}$  be a  $\mathcal{V}$ -category. A *copresheaf* over  $\mathcal{A}$  is a  $\mathcal{V}$ -functor

$$F: \mathcal{A} \rightarrow \mathcal{V}_r.$$

We denote by  $\underline{\mathbf{Hom}}(\mathcal{A}, \mathcal{V}_r)$  the category of copresheaves over  $\mathcal{A}$  and  $\mathcal{V}$ -natural transformations between them.

A *presheaf* over  $\mathcal{A}$  is a skew  $\mathcal{V}$ -functor

$$F: \mathcal{A}^t \rightarrow \mathcal{V}_l.$$

We denote by  $\underline{\mathbf{Hom}}(\mathcal{A}^t, \mathcal{V}_l)$  the category of presheaves over  $\mathcal{A}$  and skew  $\mathcal{V}$ -natural transformations between them.

**Example 1.8.** — Let  $a$  be an object of a  $\mathcal{V}$ -category  $\mathcal{A}$ . Then  $\underline{\mathbf{Hom}}_{\mathcal{A}}(a, -)$  is a copresheaf over  $\mathcal{A}$ , and  $\underline{\mathbf{Hom}}_{\mathcal{A}}(-, a)$  is a presheaf over  $\mathcal{A}$ .

As we shall now see, copresheaves and presheaves admit a useful description in terms of left and right modules.

**1.9.** — Let  $\mathcal{V}$  be a biclosed monoidal category and let  $\mathcal{A}$  be a  $\mathcal{V}$ -category. A *right  $\mathcal{A}$ -module* consists of

- a family  $(F_a)_{a \in \text{Ob}(\mathcal{A})}$  of objects of  $\mathcal{V}$ ,
- for every objects  $a$  and  $a'$  of  $\mathcal{A}$ , a morphism of  $\mathcal{V}$

$$\rho_{a,a'}: F_{a'} \otimes \underline{\mathbf{Hom}}_{\mathcal{A}}(a, a') \rightarrow F_a,$$

such that

- for every objects  $a, a'$  and  $a''$  of  $\mathcal{A}$ , the diagram

$$\begin{array}{ccc} F_{a''} \otimes \underline{\mathbf{Hom}}_{\mathcal{A}}(a', a'') \otimes \underline{\mathbf{Hom}}_{\mathcal{A}}(a, a') & \xrightarrow{F_{a''} \otimes \circ} & F_{a''} \otimes \underline{\mathbf{Hom}}_{\mathcal{A}}(a, a'') \\ \rho_{a', a''} \otimes \underline{\mathbf{Hom}}_{\mathcal{A}}(a, a') \downarrow & & \downarrow \rho_{a, a''} \\ F_{a'} \otimes \underline{\mathbf{Hom}}_{\mathcal{A}}(a, a') & \xrightarrow{\rho_{a, a'}} & F_a \end{array}$$

commutes,

- for every object  $a$  of  $\mathcal{A}$ , the diagram

$$\begin{array}{ccc} F_a \simeq F_a \otimes I & \xrightarrow{F_a \otimes 1_a} & F_a \otimes \underline{\mathbf{Hom}}_{\mathcal{A}}(a, a) \\ & \searrow = & \downarrow \rho_{a, a} \\ & & F_a \end{array}$$

commutes.

If  $F$  and  $F'$  are two right  $\mathcal{A}$ -modules, a *morphism of right  $\mathcal{A}$ -modules*  $u: F \rightarrow F'$  consists of a family  $(u_a: F_a \rightarrow F'_a)_{a \in \text{Ob}(\mathcal{A})}$  of morphisms of  $\mathcal{V}$  such that for every

objects  $a$  and  $a'$  of  $\mathcal{A}$ , the square

$$\begin{array}{ccc} F_{a'} \otimes \underline{\mathbf{Hom}}_{\mathcal{A}}(a, a') & \xrightarrow{\rho_{a, a'}} & F_a \\ u_{a'} \otimes \underline{\mathbf{Hom}}_{\mathcal{A}}(a, a') \downarrow & & \downarrow u_a \\ F'_{a'} \otimes \underline{\mathbf{Hom}}_{\mathcal{A}}(a, a') & \xrightarrow{\rho'_{a, a'}} & F'_a \end{array}$$

commutes. Right  $\mathcal{A}$ -modules and their morphisms form a category that we will denote by  $\text{Mod}_{\mathcal{A}}$ .

The notions of *left  $\mathcal{A}$ -module* and of *morphism of left  $\mathcal{A}$ -modules* are defined analogously but with an action morphism of type

$$\lambda_{a, a'}: F_a \otimes \underline{\mathbf{Hom}}_{\mathcal{A}}(a, a') \rightarrow F_{a'}.$$

We denote the category of left  $\mathcal{A}$ -modules by  ${}_{\mathcal{A}}\text{Mod}$ .

**Proposition 1.10.** — *Let  $\mathcal{V}$  be a biclosed monoidal category and let  $\mathcal{A}$  be a  $\mathcal{V}$ -category. We have isomorphisms of categories*

$${}_{\mathcal{A}}\text{Mod} \xrightarrow{\sim} \underline{\mathbf{Hom}}(\mathcal{A}, \mathcal{V}_r),$$

and

$$\text{Mod}_{\mathcal{A}} \xrightarrow{\sim} \underline{\mathbf{Hom}}(\mathcal{A}^t, \mathcal{V}_l).$$

*Proof.* — This follows from the adjunctions between the tensor product and  $\underline{\mathbf{Hom}}_r$  and  $\underline{\mathbf{Hom}}_l$ . We leave the details to the reader.  $\square$

**Remark 1.11.** — In practice, in this paper, we will produce presheaves and then use the previous proposition to obtain right modules and do computations using the laws of right modules.

As we shall see in the next section, one specific property of the Gray tensor product is that its monoidal unit is the terminal object. We now develop some enriched category theory with this additional hypothesis.

**1.12.** — A monoidal category  $(\mathcal{V}, \otimes, I)$  is said to be *with projections* if  $\mathcal{V}$  admits finite products and the tensor unit of  $\mathcal{V}$  is a terminal object. In this case, if  $X$  and  $Y$  are two objects of  $\mathcal{V}$ , we get “projections”

$$X \xleftarrow{\sim} X \otimes I \xleftarrow{X \otimes p_X} X \otimes Y \xrightarrow{p_Y \otimes Y} I \otimes Y \xrightarrow{\sim} Y, \quad ,$$

where  $p_Z: Z \rightarrow I$  denotes the unique morphism to the terminal object. In particular, we get a morphism

$$\pi = (\pi_1, \pi_2): X \otimes Y \rightarrow X \times Y,$$

natural in  $X$  and  $Y$  in  $\mathcal{V}$ .

The cartesian product defines a monoidal structure on  $\mathcal{V}$  and we will denote by  $\mathcal{V}^\times$  the resulting monoidal category. By default,  $\mathcal{V}$  will be endowed with the monoidal

product  $\otimes$  but sometimes, to emphasize this, we will denote this monoidal category by  $\mathcal{V}^\otimes$ .

With this notation, the morphism  $\pi$  shows that the identity functor of  $\mathcal{V}$  is a lax monoidal functor from  $\mathcal{V}^\times$  to  $\mathcal{V}^\otimes$ . It is also lax monoidal considered with values in  $\overline{\mathcal{V}^\otimes}$ . In particular, we get 2-functors

$$\mathcal{V}^\times\text{-Cat} \rightarrow \mathcal{V}^\otimes\text{-Cat} \quad \text{and} \quad \mathcal{V}^\times\text{-Cat} \rightarrow \overline{\mathcal{V}^\otimes}\text{-Cat}.$$

If the morphism  $\pi: X \otimes Y \rightarrow X \times Y$  is an epimorphism for every objects  $X$  and  $Y$  of  $\mathcal{V}$ , we will say that  $\mathcal{V}$  has *jointly surjective projections*. In this case, the two 2-functors above are injective on objects and fully faithful.

Suppose moreover that  $\mathcal{V}$  is cartesian closed and that  $\mathcal{V}^\otimes$  is monoidal biclosed. We will denote by  $\mathcal{V}_{\text{cart}}$  the  $\mathcal{V}^\times$ -category obtained by enriching  $\mathcal{V}$  over itself using the cartesian internal  $\underline{\text{Hom}}$ . In other words, if  $X$  and  $Y$  are two objects of  $\mathcal{V}$ , then  $\underline{\text{Hom}}_{\mathcal{V}_{\text{cart}}}(X, Y) = \underline{\text{Hom}}(X, Y)$ , where  $\underline{\text{Hom}}$  denotes the cartesian internal  $\underline{\text{Hom}}$  of  $\mathcal{V}$ . Based on the above,  $\mathcal{V}_{\text{cart}}$  can also be considered as either a  $\mathcal{V}^\otimes$ -category or a  $\overline{\mathcal{V}^\otimes}$ -category. By the Yoneda lemma, using the morphism  $\pi$ , we get canonical morphisms

$$\underline{\text{Hom}}_{\mathcal{V}}(X, Y) \rightarrow \underline{\text{Hom}}_r(X, Y) \quad \text{and} \quad \underline{\text{Hom}}_{\mathcal{V}}(X, Y) \rightarrow \underline{\text{Hom}}_l(X, Y).$$

These morphisms are monomorphisms if  $\mathcal{V}$  has jointly surjective projections. In any case, they induce a  $\mathcal{V}^\otimes$ -functor and a  $\overline{\mathcal{V}^\otimes}$ -functor

$$\mathcal{V}_{\text{cart}} \rightarrow \mathcal{V}_r \quad \text{and} \quad \mathcal{V}_{\text{cart}} \rightarrow \mathcal{V}_l.$$

**1.13.** — Let  $\mathcal{V}$  be a monoidal category with projections. If  $X, Y$  and  $Z$  are three objects of  $\mathcal{V}$ , we have a canonical natural morphism

$$\varphi: X \otimes (Y \times Z) \rightarrow (X \otimes Y) \times Z,$$

given on components by

$$X \otimes (Y \times Z) \xrightarrow{X \otimes p_1} X \otimes Y \quad \text{and} \quad X \otimes (Y \times Z) \xrightarrow{\pi_2} Y \times Z \xrightarrow{p_2} Z,$$

where  $p_1$  and  $p_2$  denote the projections of the cartesian product, and  $\pi_1$  and  $\pi_2$  the “projections” of the tensor product. We will not need this fact but one can show that  $\varphi$  is a tensorial strength on the functor  $- \times Z$ .

Suppose moreover that  $\mathcal{V}$  is cartesian closed and monoidal biclosed. Then the morphism  $\varphi$  induces a natural morphism

$$\lambda: \underline{\text{Hom}}_l(X, \underline{\text{Hom}}(Y, Z)) \rightarrow \underline{\text{Hom}}(Y, \underline{\text{Hom}}_l(X, Z))$$

that makes the following square commutative

$$\begin{array}{ccc} \underline{\text{Hom}}_l(X, \underline{\text{Hom}}(Y, Z)) & \xrightarrow{\lambda} & \underline{\text{Hom}}(Y, \underline{\text{Hom}}_l(X, Z)) \\ \downarrow & & \downarrow \\ \underline{\text{Hom}}_l(X, \underline{\text{Hom}}_r(Y, Z)) & \xrightarrow{\sim} & \underline{\text{Hom}}_r(Y, \underline{\text{Hom}}_l(X, Z)) \end{array},$$

where the vertical arrows are induced by the canonical morphism from  $\underline{\mathbf{Hom}}$  to  $\underline{\mathbf{Hom}}_r$ . Explicitly, the morphism  $\lambda$  is obtained by adjunction from

$$\begin{array}{c} X \otimes (\underline{\mathbf{Hom}}_l(X, \underline{\mathbf{Hom}}(Y, Z)) \times Y) \\ \downarrow \varphi \\ (X \otimes \underline{\mathbf{Hom}}_l(X, \underline{\mathbf{Hom}}(Y, Z))) \times Y \xrightarrow{\text{ev} \times Y} \underline{\mathbf{Hom}}(Y, Z) \times Y \xrightarrow{\text{ev}} Z \quad , \end{array}$$

where  $\text{ev}$  denotes the two evaluation morphisms. It follows from the commutative square above that if  $\mathcal{V}$  has jointly surjective projections, then  $\lambda$  is a monomorphism.

**Remark 1.14.** — The previous paragraph can be dualized to  $\underline{\mathbf{Hom}}_r$ . In particular, there is a canonical natural morphism

$$\underline{\mathbf{Hom}}_r(X, \underline{\mathbf{Hom}}(Y, Z)) \rightarrow \underline{\mathbf{Hom}}(Y, \underline{\mathbf{Hom}}_r(X, Z)) .$$

## 2. Preliminaries on strict $\omega$ -categories and Gray $\omega$ -categories

**2.1.** — For any  $n \geq 1$ , we denote by  $n\text{-Cat}$  the category of (small) strict  $n$ -categories and strict  $n$ -functors, that is, the category of categories enriched in  $(n-1)\text{-Cat}$  (with the cartesian monoidal structure), the category  $0\text{-Cat}$  being the category  $\mathcal{S}et$  of sets.

We have a canonical inclusion

$$(n-1)\text{-Cat} \hookrightarrow n\text{-Cat}$$

sending a strict  $(n-1)$ -category to the strict  $n$ -category obtained by adding only trivial  $n$ -cells (that is, identities). This inclusion admits a right adjoint  $\tau_{n-1}: n\text{-Cat} \rightarrow (n-1)\text{-Cat}$ , and the category  $\omega\text{-Cat}$  of strict  $\omega$ -categories and strict  $\omega$ -functors is obtained as the limit of the diagram

$$\dots \longrightarrow 2\text{-Cat} \xrightarrow{\tau_1} 1\text{-Cat} \xrightarrow{\tau_0} 0\text{-Cat} \quad .$$

For any  $n \geq 0$ , we have a canonical fully faithful functor

$$n\text{-Cat} \hookrightarrow \omega\text{-Cat} ,$$

admitting both a left and a right adjoint, and whose image consists exactly of those strict  $\omega$ -categories with only trivial  $k$ -cells for  $k > n$ . We shall always consider the previous fully faithful functor as an inclusion.

From now on, we will drop the adjective “strict” and simply refer to “strict  $\omega$ -categories” and “strict  $\omega$ -functors” as “ $\omega$ -categories” and “ $\omega$ -functors” (and similarly for “ $n$ -categories” and “ $n$ -functors”).

Let us introduce some notation.

**2.2.** — Let  $C$  be an  $\omega$ -category. If  $x$  is a  $k$ -cell of  $C$ , for  $0 \leq i \leq k$ , we denote by

$$s_i(x) \quad \text{and} \quad t_i(x)$$

the  $i$ -dimensional source and target of  $x$ , also called  $i$ -source and  $i$ -target of  $x$ . In the case where  $i = k - 1$ , we also write  $s(x)$  and  $t(x)$ . For  $i \geq k$ , we denote by

$$1_x^i$$

the  $i$ -dimensional unit of  $x$ . When  $i = k + 1$ , we also write  $1_x$ .

Given two  $k$ -cells  $x$  and  $y$  such that  $s_i(x) = t_i(y)$ , with  $i < k$ , we denote by

$$x *_i y$$

their  $i$ -composition. More generally, for  $k > i$  and  $l > i$ ,  $x$  a  $k$ -cell and  $y$  an  $l$ -cell such that  $s_i(x) = t_i(y)$ , then if  $k \leq l$ , we set

$$x *_i y = 1_x^l *_i y,$$

and if  $k \geq l$ , we set

$$x *_i y = x *_i 1_y^l.$$

**2.3.** — For any  $n \geq 0$ , we define  $D_n$  to be the  $n$ -category freely generated by a generic  $n$ -cell. Explicitly,  $D_n$  has exactly one non-trivial  $n$ -cell  $e_n$ , and exactly two non-trivial  $k$ -cells for  $0 \leq k < n$  given by  $s_k(e_n)$  and  $t_k(e_n)$ .

$$D_0 = \bullet, \quad D_1 = \bullet \longrightarrow \bullet, \quad D_2 = \bullet \begin{array}{c} \curvearrowright \\ \Downarrow \\ \curvearrowleft \end{array} \bullet, \quad \dots$$

In particular,  $D_n$  represents the functor  $\omega\text{-Cat} \rightarrow \text{Set}$  that sends an  $\omega$ -category to its set of  $n$ -cells. If  $x$  is an  $n$ -cell of an  $\omega$ -category  $C$ , we will denote by  $\tilde{x}: D_n \rightarrow C$  the corresponding  $\omega$ -functor.

**2.4.** — The category  $\omega\text{-Cat}$  has several interesting monoidal structures. First, it is cartesian closed and the associated internal  $\mathbf{Hom}$  will be denoted by

$$\underline{\mathbf{Hom}}(A, B),$$

for  $A$  and  $B$  two  $\omega$ -categories. The  $n$ -cells of this  $\omega$ -category are in bijection with the  $\omega$ -functors

$$D_n \times A \rightarrow B.$$

In particular, the 0-cells are simply the  $\omega$ -functors  $A \rightarrow B$ . For  $n \geq 1$ , the  $n$ -cells are referred to as *strict  $n$ -transformations*. Explicitly, given two  $\omega$ -functors  $u, v: A \rightarrow B$ , a strict  $n$ -transformation  $\alpha$ , with 0-source  $u$  and 0-target  $v$ , is a family  $(\alpha_x)$  of  $n$ -cells of  $B$ , indexed by the 0-cells  $x$  of  $A$ , such that

- for every 0-cell  $x$  of  $A$ , we have

$$s_0(\alpha_x) = u(x) \quad \text{and} \quad t_0(\alpha_x) = v(x),$$

- for every  $k$ -cell  $x$  of  $C$ , with  $k \geq 1$ , we have

$$\alpha_{t_0(x)} *_0 u(x) = v(x) *_0 \alpha_{s_0(x)}.$$

The category  $\omega\text{-Cat}$  is enriched over itself via the cartesian product, and we have a “fixed point” property: the category of categories enriched in  $(\omega\text{-Cat}, \times, D_0)$  is canonically isomorphic to  $\omega\text{-Cat}$  itself. In particular, we have a (large)  $\omega$ -category

$$\omega\text{-Cat}_{\text{cart}},$$

whose 0-cells are (small)  $\omega$ -categories, whose 1-cells are  $\omega$ -functors and whose  $n$ -cells, with  $n > 1$ , are strict  $(n - 1)$ -transformations.

**2.5.** — Another fundamental monoidal structure on  $\omega\text{-Cat}$  comes from the so-called (*oplax*) *Gray tensor product* (see for example [4, Appendix A]), denoted by  $\otimes$ . To give an intuition, the tensor product  $D_1 \otimes D_1$  is a square with a non-trivial 2-cell

$$\begin{array}{ccc} \bullet & \longrightarrow & \bullet \\ \downarrow & \swarrow & \downarrow \\ \bullet & \longrightarrow & \bullet \end{array},$$

whereas the cartesian product  $D_1 \times D_1$  is a commutative square. The monoidal unit is the terminal  $\omega$ -category  $D_0$  (as for the cartesian structure) and the Gray tensor product thus defines a monoidal structure with projections in the sense of 1.12. This monoidal structure is *not* symmetrical (and not even braided). For example, we have

$$D_1 \otimes D_2 = \begin{array}{ccc} \bullet & \xrightarrow{\quad} & \bullet \\ \downarrow & \swarrow & \downarrow \\ \bullet & \xrightarrow{\quad} & \bullet \end{array} \begin{array}{c} \downarrow \\ \downarrow \end{array} \cong \begin{array}{ccc} \bullet & \xrightarrow{\quad} & \bullet \\ \downarrow & \swarrow & \downarrow \\ \bullet & \xrightarrow{\quad} & \bullet \end{array} \begin{array}{c} \downarrow \\ \downarrow \end{array}$$

and

$$D_2 \otimes D_1 = \begin{array}{ccc} \bullet & \xrightarrow{\quad} & \bullet \\ \downarrow & \swarrow & \downarrow \\ \bullet & \xrightarrow{\quad} & \bullet \end{array} \begin{array}{c} \leftarrow \\ \leftarrow \end{array} \cong \begin{array}{ccc} \bullet & \xrightarrow{\quad} & \bullet \\ \downarrow & \swarrow & \downarrow \\ \bullet & \xrightarrow{\quad} & \bullet \end{array} \begin{array}{c} \leftarrow \\ \leftarrow \end{array}.$$

**2.6.** — Let  $A$  and  $B$  be two  $\omega$ -categories. If  $x$  is a  $k$ -cell of  $A$  and  $y$  an  $l$ -cell of  $B$ , then there is an associated  $(k + l)$ -cell  $x \otimes y$  in  $A \otimes B$ . Explicitly, with the notation of 2.3, this cell corresponds to the  $\omega$ -functor

$$D_{k+l} \xrightarrow{\tilde{c}} D_k \otimes D_l \xrightarrow{\tilde{x} \otimes \tilde{y}} A \otimes B,$$

where  $c$  denotes the *principal cell* of  $D_k \otimes D_l$ , that is, its unique non-trivial  $(k + l)$ -cell (see for instance [3, paragraph B.1.5]).

We will not need this fact in this paper but one can show that cells of the form  $x \otimes y$  generate  $A \otimes B$  under composition.

**2.7.** — The Gray tensor product is biclosed, with internal  $\mathbf{Hom}$  denoted by  $\underline{\mathbf{Hom}}_{\text{oplax}}$  and  $\underline{\mathbf{Hom}}_{\text{lax}}$ , respectively, so that we have

$$\begin{aligned} \mathbf{Hom}(A \otimes B, C) &\simeq \mathbf{Hom}(A, \underline{\mathbf{Hom}}_{\text{oplax}}(B, C)) \\ &\simeq \mathbf{Hom}(B, \underline{\mathbf{Hom}}_{\text{lax}}(A, C)), \end{aligned}$$

for  $A$ ,  $B$  and  $C$  three  $\omega$ -categories. Moreover, by 1.5, this last bijection can be promoted to a natural isomorphism

$$\underline{\mathbf{Hom}}_{\text{lax}}(A, \underline{\mathbf{Hom}}_{\text{oplax}}(B, C)) \simeq \underline{\mathbf{Hom}}_{\text{oplax}}(B, \underline{\mathbf{Hom}}_{\text{lax}}(A, C)).$$

The  $n$ -cells of  $\underline{\mathbf{Hom}}_{\text{oplax}}(A, B)$  (resp. of  $\underline{\mathbf{Hom}}_{\text{lax}}(A, B)$ ) are in bijection with the  $\omega$ -functors

$$D_n \otimes A \rightarrow B \quad (\text{resp. } A \otimes D_n \rightarrow B).$$

In particular, the 0-cells of both  $\underline{\mathbf{Hom}}_{\text{oplax}}(A, B)$  and  $\underline{\mathbf{Hom}}_{\text{lax}}(A, B)$  are simply the  $\omega$ -functors  $A \rightarrow B$ . For  $n \geq 1$ , an  $n$ -cell of  $\underline{\mathbf{Hom}}_{\text{oplax}}(A, B)$  (resp. of  $\underline{\mathbf{Hom}}_{\text{lax}}(A, B)$ ) is called an *oplax  $n$ -transformation* (resp. a *lax  $n$ -transformation*). For  $n = 1$ , we will simply say *oplax transformations* (resp. *lax transformations*). For an explicit description of oplax transformations, see for example [4, paragraph 1.9].

**2.8.** — By definition, if  $u, v: A \rightarrow B$  are two  $\omega$ -functors, an oplax transformation  $\alpha$  from  $u$  to  $v$  corresponds to an  $\omega$ -functor  $h: D_1 \otimes A \rightarrow B$  making the following diagram commutative

$$\begin{array}{ccc} D_0 \otimes A \simeq A & & \xrightarrow{u} \\ \sigma \otimes A \downarrow & & \searrow \\ D_1 \otimes A & \xrightarrow{h} & A \\ \tau \otimes A \uparrow & & \nearrow \\ D_0 \otimes A \simeq A & & \xrightarrow{v} \end{array},$$

where  $\sigma, \tau: D_0 \rightarrow D_1$  correspond to the source and the target of the non-trivial 1-cell of  $D_1$ . By adjunction, it also corresponds to an  $\omega$ -functor  $k: A \rightarrow \underline{\mathbf{Hom}}_{\text{lax}}(D_1, B)$  making the diagram

$$\begin{array}{ccc} & B \simeq \underline{\mathbf{Hom}}_{\text{lax}}(D_0, B) & \\ \begin{array}{c} \nearrow u \\ \searrow v \end{array} & & \uparrow \underline{\mathbf{Hom}}_{\text{lax}}(\sigma, B) \\ A & \xrightarrow{k} & \underline{\mathbf{Hom}}_{\text{lax}}(D_1, B) \\ & & \downarrow \underline{\mathbf{Hom}}_{\text{lax}}(\tau, B) \\ & B \simeq \underline{\mathbf{Hom}}_{\text{lax}}(D_0, B) & \end{array}$$

commute. This leads us to set

$$\Gamma B = \underline{\mathbf{Hom}}_{\text{lax}}(D_1, B).$$

This  $\omega$ -category is the  *$\omega$ -category of cylinders in  $B$* . A  $k$ -cell in this  $\omega$ -category is called a  *$k$ -cylinder in  $B$* . In other words, a  $k$ -cylinder in  $B$  is an  $\omega$ -functor  $D_1 \otimes D_k \rightarrow B$ .

If  $\beta: D_1 \otimes D_k \rightarrow B$  is such a  $k$ -cylinder, the image of the principal cell of  $D_1 \otimes D_k$  (see 2.6) in  $B$  will be called the *principal cell* of  $\beta$ . We will denote it by  $\beta_k$ .

As a particular case of the compatibilities between  $\underline{\mathbf{Hom}}_{\text{lax}}$  and  $\underline{\mathbf{Hom}}_{\text{oplax}}$  (see 2.7), we get that if  $A$  and  $B$  are two  $\omega$ -categories, then we have a natural isomorphism

$$\Gamma \underline{\mathbf{Hom}}_{\text{oplax}}(A, B) \simeq \underline{\mathbf{Hom}}_{\text{oplax}}(A, \Gamma B).$$

This isomorphism will play an important role in this paper.

In [5, Section 4] (see also [6, Appendix A]), the authors describe the  $\omega$ -category  $\Gamma C$  inductively. The two following paragraphs provide preliminaries to phrase their description.

**2.9.** — If  $C$  is an  $\omega$ -category, then the  $\omega$ -category  $\Gamma C$  is naturally the object of morphisms of a category internal to  $\omega\text{-Cat}$ . Indeed, the functors

$$\sigma, \tau: D_0 \rightarrow D_1, \quad \kappa: D_1 \rightarrow D_0 \quad \text{and} \quad \nabla: D_1 \rightarrow D_1 \amalg_{D_0} D_1,$$

corresponding respectively to the source and the target of the unique non-trivial 1-cell of  $D_1$ , the unit of the unique object of  $D_0$  and the total composition of  $D_1 \amalg_{D_0} D_1$ , define a cocategory internal to categories, and hence internal to  $\omega$ -categories. By applying the functor  $\underline{\mathbf{Hom}}_{\text{lax}}(-, C)$  which sends colimits to limits, we get  $\omega$ -functors

$$\mathfrak{s}, \mathfrak{t}: \Gamma C \rightarrow C, \quad \mathfrak{k}: C \rightarrow \Gamma C \quad \text{and} \quad *_c: \Gamma C \times_C \Gamma C \rightarrow \Gamma C$$

defining a structure of category internal to  $\omega$ -categories. If  $x$  is a cell of  $C$ , we will denote  $\mathfrak{k}(x)$  by  $\mathbb{1}_x$ .

**2.10.** — Let  $C$  be an  $\omega$ -category and let  $c$  and  $d$  be two objects of  $C$ . For every 1-cell  $u: c' \rightarrow c$ , we have an  $\omega$ -functor

$$\Gamma \underline{\mathbf{Hom}}_C(u, d): \Gamma \underline{\mathbf{Hom}}_C(c, d) \rightarrow \Gamma \underline{\mathbf{Hom}}_C(c', d).$$

If  $\alpha$  is a cell in  $\Gamma \underline{\mathbf{Hom}}_C(c, d)$ , we will denote its image by this  $\omega$ -functor by  $\alpha *_r u$ .

Similarly, if  $v: d \rightarrow d'$  is a 1-cell of  $C$ , we have an  $\omega$ -functor

$$\Gamma \underline{\mathbf{Hom}}_C(c, v): \Gamma \underline{\mathbf{Hom}}_C(c, d) \rightarrow \Gamma \underline{\mathbf{Hom}}_C(c, d'),$$

and if  $\alpha$  is a cell in  $\Gamma \underline{\mathbf{Hom}}_C(c, d)$ , its image will be denoted by  $v *_l \alpha$ .

**Remark 2.11.** — We will come back to these operations in terms of modules in 4.2 and Remark 4.6.

**2.12.** — Let  $C$  be an  $\omega$ -category. By [5, Section 4], the  $\omega$ -category  $\Gamma C$  can be described (up to isomorphism) as a category enriched in  $\omega$ -categories in the following way:

- The objects of  $\Gamma C$  are the 1-cells of  $C$ .

- If  $f: c \rightarrow d$  and  $f': c' \rightarrow d'$  are two objects of  $\Gamma C$ , we have

$$\begin{aligned} & \underline{\mathbf{Hom}}_{\Gamma C}(f, f') \\ &= \underline{\mathbf{Hom}}_C(c, c') \times_{\underline{\mathbf{Hom}}_C(c, d')} \Gamma \underline{\mathbf{Hom}}_C(c, d') \times_{\underline{\mathbf{Hom}}_C(c, d')} \underline{\mathbf{Hom}}_C(d, d'), \end{aligned}$$

where this iterated fiber product denotes the limit of the diagram

$$\begin{array}{ccccc} \underline{\mathbf{Hom}}_C(c, c') & & \Gamma \underline{\mathbf{Hom}}_C(c, d') & & \underline{\mathbf{Hom}}_C(d, d') \\ & \searrow^{f' *_0 -} & \swarrow^{\mathfrak{s}} & \searrow^{\mathfrak{t}} & \swarrow^{-*_0 f} \\ & \underline{\mathbf{Hom}}_C(c, d') & & \underline{\mathbf{Hom}}_C(c, d') & \end{array} .$$

Concretely, a  $k$ -cell in this  $\mathbf{Hom}$  is a triple  $(u, \alpha, v)$  in

$$\underline{\mathbf{Hom}}_C(c, c')_k \times \Gamma \underline{\mathbf{Hom}}_C(c, d')_k \times \underline{\mathbf{Hom}}_C(d, d')_k$$

such that

$$\mathfrak{s}(\alpha) = f' *_0 u \quad \text{and} \quad \mathfrak{t}(\alpha) = v *_0 f. \quad (*)$$

This formula is an  $\omega$ -categorification of the formula for a 1-cylinder, i.e., a 2-square:

$$\begin{array}{ccc} c & \xrightarrow{u} & c' \\ f \downarrow & \alpha \swarrow & \downarrow f' \\ d & \xrightarrow{v} & d' \end{array} .$$

In other words, a  $(k+1)$ -cylinder in  $C$  is given by its 0-source  $f: c \rightarrow d$  and its 0-target  $f': c' \rightarrow d'$ , a  $k$ -cell  $u$  in  $C$  of 0-source  $c$  and 0-target  $c'$ , a  $k$ -cell  $v$  in  $C$  of 0-source  $d$  and 0-target  $d'$ , and a  $k$ -cylinder  $\alpha$  in  $\underline{\mathbf{Hom}}_C(c, d')$  satisfying the relations  $(*)$ .

- If  $f, f', f''$  are three objects of  $\Gamma C$ , the composition  $\omega$ -functor

$$\underline{\mathbf{Hom}}_{\Gamma C}(f', f'') \times \underline{\mathbf{Hom}}_{\Gamma C}(f, f') \rightarrow \underline{\mathbf{Hom}}_{\Gamma C}(f, f'')$$

is given by

$$((u', \alpha', v'), (u, \alpha, v)) \mapsto (u' *_0 u, (v' *_l \alpha) *_c (\alpha' *_r u), v' *_0 v).$$

This formula is an  $\omega$ -categorification of the formula for composing the diagram

$$\begin{array}{ccccc} c & \xrightarrow{u} & c' & \xrightarrow{u'} & c'' \\ f \downarrow & \alpha \swarrow & \downarrow f' & \alpha' \swarrow & \downarrow f'' \\ d & \xrightarrow{v} & d' & \xrightarrow{v'} & d'' \end{array} .$$

- If  $f: c \rightarrow d$  is an object of  $\Gamma C$ , its unit is the 1-cylinder  $(1_c, \mathbb{1}_f, 1_d)$ , corresponding to the commutative square

$$\begin{array}{ccc}
 c & \xrightarrow{1_c} & c \\
 f \downarrow & \swarrow \mathbb{1}_f & \downarrow f \\
 d & \xrightarrow{1_d} & d
 \end{array} .$$

We now come to one of the central notions of this paper, the notion of a Gray  $\omega$ -category, introduced in [4, Appendix C]:

**2.13.** — A *Gray  $\omega$ -category* is a  $\mathcal{V}$ -category for  $\mathcal{V} = (\omega\text{-Cat}, \otimes, D_0)$  and a *skew Gray  $\omega$ -category* a skew  $\mathcal{V}$ -category, again for  $\mathcal{V} = (\omega\text{-Cat}, \otimes, D_0)$ .

If  $\mathbb{C}$  is a Gray  $\omega$ -category, its objects will also be called *0-cells*. If  $c$  and  $d$  are two 0-cells of  $\mathbb{C}$ , the  $k$ -cells of the  $\omega$ -category  $\underline{\text{Hom}}_{\mathbb{C}}(c, d)$  will be called  $(k+1)$ -cells of  $\mathbb{C}$ . By definition, if  $x$  is such a cell, the *0-source*  $s_0(x)$  of  $x$  is  $c$  and its *0-target*  $t_0(x)$  is  $d$ . The composition of  $x *_i y$  of two  $k$ -cells of  $\underline{\text{Hom}}_{\mathbb{C}}(c, d)$  will be denoted by  $x *_i y$  if the cells  $x$  and  $y$  are considered as  $(k+1)$ -cells of  $\mathbb{C}$ .

If  $a, b$  and  $c$  are three 0-cells of  $\mathbb{C}$ , the composition  $\omega$ -functor will be denoted by

$$*_0: \underline{\text{Hom}}_{\mathbb{C}}(b, c) \otimes \underline{\text{Hom}}_{\mathbb{C}}(a, b) \rightarrow \underline{\text{Hom}}_{\mathbb{C}}(a, c).$$

If  $x$  is a  $k$ -cell of 0-source  $b$  and 0-target  $c$  and  $y$  is an  $l$ -cell of 0-source  $a$  and 0-target  $b$ , we will denote by  $x *_0 y$  the cell obtained by applying the composition  $\omega$ -functor to the  $(k+l-2)$ -cell  $x \otimes y$  of  $\underline{\text{Hom}}_{\mathbb{C}}(b, c) \otimes \underline{\text{Hom}}_{\mathbb{C}}(a, b)$ . This cell is a  $(k+l-2)$ -cell of  $\underline{\text{Hom}}_{\mathbb{C}}(a, c)$ . In other words,  $x *_0 y$  is a  $(k+l-1)$ -cell of  $\mathbb{C}$ . Its 0-source is  $a$  and its 0-target  $c$ . Note that the composition  $\omega$ -functor is uniquely determined by all the  $x *_0 y$ .

In particular, the composition  $*_0$  of a  $k$ -cell and 1-cell of  $\mathbb{C}$  is a  $k$ -cell. The composition  $x *_0 y$  of two 2-cells of  $\mathbb{C}$  is a 3-cell. In general, the exchange rule in  $\mathbb{C}$  for the cells  $x$  and  $y$  do not hold on the nose but up to the non-invertible 3-cell  $x *_0 y$ :

$$(x *_0 t(y)) *_1 (s(x) *_0 y) \xrightarrow{x *_0 y} (t(x) *_0 y) *_1 (\beta *_0 s(y))$$

(see [3, Proposition B.1.14]). We refer the reader to [3, Section B.1] for more details on the elementary structure of Gray  $\omega$ -categories.

Similar definitions and notation apply to skew Gray  $\omega$ -categories.

**2.14.** — Enriched functors between Gray  $\omega$ -categories will be called *Gray  $\omega$ -functors*. Similarly, enriched functors between skew Gray  $\omega$ -categories will be called *skew Gray  $\omega$ -functors*. A Gray or skew Gray  $\omega$ -functor is uniquely determined by its action on cells. More precisely, morphisms between Gray or skew Gray  $\omega$ -categories can be described as functions on  $k$ -cells for every  $k \geq 0$  that are compatible with sources, targets, compositions and units.

Enriched natural transformations between Gray or skew Gray  $\omega$ -functors will be called *strict transformations*. Explicitly, if  $F, G: \mathbb{C} \rightarrow \mathbb{C}'$  are two Gray  $\omega$ -functors (or two skew Gray  $\omega$ -functors), a strict transformation  $\alpha: F \Rightarrow G$  consists of the data of a 1-cell

$$\alpha_c: F(c) \rightarrow G(c)$$

for every 0-cell  $c$  of  $\mathbb{C}$ , such that, for every  $k$ -cell  $x$  of  $\mathbb{C}$ , with  $k \geq 1$ , we have

$$\alpha_{t_0(x)} *_{\mathbb{0}} F(x) = G(x) *_{\mathbb{0}} \alpha_{s_0(x)}.$$

**2.15.** — We will denote by

$$\omega\text{-Cat}_{\text{oplax}} \quad (\text{resp. } \omega\text{-Cat}_{\text{lax}})$$

the Gray  $\omega$ -category (resp. the skew Gray  $\omega$ -category) whose objects are  $\omega$ -categories and whose  $\text{Hom}$  are

$$\underline{\text{Hom}}_{\text{oplax}}(A, B) \quad (\text{resp. } \underline{\text{Hom}}_{\text{lax}}(A, B)),$$

where  $A$  and  $B$  are two  $\omega$ -categories. By definition, the 0-cells of  $\omega\text{-Cat}_{\text{oplax}}$  (resp. of  $\omega\text{-Cat}_{\text{lax}}$ ) are  $\omega$ -categories, its 1-cells are  $\omega$ -functors, its 2-cells are oplax (resp. lax) transformations and, for  $n > 2$ , its  $n$ -cells are oplax (resp. lax)  $(n-1)$ -transformations.

**2.16.** — Since the monoidal unit of the Gray tensor product is the terminal  $\omega$ -category, by 1.12, for every  $\omega$ -categories  $A$  and  $B$ , we have a canonical  $\omega$ -functor

$$\pi = (\pi_1, \pi_2): A \otimes B \rightarrow A \times B.$$

**Proposition 2.17.** — *If  $A$  and  $B$  are two  $\omega$ -categories, the  $\omega$ -functor*

$$\pi: A \otimes B \rightarrow A \times B$$

*is an epimorphism.*

*Proof.* — The  $\omega$ -category  $A \times B$  is generated under composition by cells of the form  $(x, 1_b^k)$ , where  $x$  is a  $k$ -cell of  $A$ , with  $k \geq 0$ , and  $b$  a 0-cell of  $B$ , and of the form  $(1_a^l, y)$ , where  $a$  is a 0-cell of  $A$  and  $y$  an  $l$ -cell of  $B$ , with  $l \geq 0$ . It thus suffices to show that these cells are in the image of the  $\omega$ -functor  $\pi$ . But if  $b$  is a 0-cell of  $B$ , considering the commutative diagram

$$\begin{array}{ccc} A \otimes D_0 & \xrightarrow{A \otimes b} & A \otimes B \\ \wr \downarrow \pi & & \downarrow \pi \\ A \times D_0 & \xrightarrow{A \times b} & A \times B \end{array},$$

we get that for every  $k$ -cell  $x$  of  $A$ , the cell  $(x, 1_b^k)$  is in the image of  $\pi: A \otimes B \rightarrow A \times B$ . A similar argument shows that cells of the form  $(1_a^l, y)$  are in the image of  $\pi$ , thereby proving the result.  $\square$

**Remark 2.18.** — We will not need this but one can actually prove that the  $\omega$ -functor  $\pi$  of the proposition is surjective on cells. More precisely, if  $x$  is a  $k$ -cell of  $A$  and  $y$  is an  $l$ -cell of  $B$ , then we have  $\pi(x \otimes y) = (1_x^{k+l}, 1_y^{k+l})$ .

**2.19.** — In the language of 1.12, the previous proposition states that the monoidal category  $(\omega\text{-Cat}, \otimes, D_0)$  has jointly surjective projections. We can thus apply the considerations of 1.12 and 1.13. Let us start by 1.12.

We get that the category of  $\omega$ -categories embeds both in the category of Gray  $\omega$ -categories and in the category of skew Gray  $\omega$ -categories. Moreover, we have canonical monomorphisms

$$\underline{\mathbf{Hom}}(A, B) \hookrightarrow \underline{\mathbf{Hom}}_{\text{oplax}}(A, B) \quad \text{and} \quad \underline{\mathbf{Hom}}(A, B) \hookrightarrow \underline{\mathbf{Hom}}_{\text{lax}}(A, B),$$

which we will treat as inclusions.

We thus have canonical Gray and skew Gray  $\omega$ -functors

$$\omega\text{-Cat}_{\text{cart}} \hookrightarrow \omega\text{-Cat}_{\text{oplax}} \quad \text{and} \quad \omega\text{-Cat}_{\text{cart}} \hookrightarrow \omega\text{-Cat}_{\text{lax}},$$

which are the identity on objects and faithful.

**2.20.** — Let us now apply 1.13 to  $(\omega\text{-Cat}, \otimes, D_0)$ . If  $D, A, B$  are three  $\omega$ -categories, we have a canonical monomorphism

$$\lambda: \underline{\mathbf{Hom}}_{\text{lax}}(D, \underline{\mathbf{Hom}}(A, B)) \hookrightarrow \underline{\mathbf{Hom}}(A, \underline{\mathbf{Hom}}_{\text{lax}}(D, B))$$

that makes the square

$$\begin{array}{ccc} \underline{\mathbf{Hom}}_{\text{lax}}(D, \underline{\mathbf{Hom}}(A, B)) & \xleftarrow{\lambda} & \underline{\mathbf{Hom}}(A, \underline{\mathbf{Hom}}_{\text{lax}}(D, B)) \\ \downarrow & & \downarrow \\ \underline{\mathbf{Hom}}_{\text{lax}}(D, \underline{\mathbf{Hom}}_{\text{oplax}}(A, B)) & \xrightarrow{\sim} & \underline{\mathbf{Hom}}_{\text{oplax}}(A, \underline{\mathbf{Hom}}_{\text{lax}}(D, B)) \end{array}$$

commute. We will treat  $\lambda$  as an inclusion. We thus get a factorization

$$\underline{\mathbf{Hom}}_{\text{lax}}(D, \underline{\mathbf{Hom}}(A, B)) \hookrightarrow \underline{\mathbf{Hom}}(A, \underline{\mathbf{Hom}}_{\text{lax}}(D, B)) \hookrightarrow \underline{\mathbf{Hom}}_{\text{lax}}(D, \underline{\mathbf{Hom}}_{\text{oplax}}(A, B))$$

of the canonical inclusion. This applies in particular to the case where  $D = D_1$  in which we get inclusions

$$\Gamma \underline{\mathbf{Hom}}(A, B) \hookrightarrow \underline{\mathbf{Hom}}(A, \Gamma B) \hookrightarrow \Gamma \underline{\mathbf{Hom}}_{\text{oplax}}(A, B).$$

We end the section by some considerations on the dualities of  $\omega\text{-Cat}$ .

**2.21.** — If  $S \subset \mathbb{N}^*$  is a subset of the set of positive integers, then we will denote by

$$D_S: \omega\text{-Cat} \rightarrow \omega\text{-Cat}$$

the  $\omega$ -functor sending an  $\omega$ -category  $C$  to the  $\omega$ -category obtained from  $C$  by reversing the orientation of all the cells whose dimension belongs to  $S$ . It is immediate that  $D_S$  is an involutive endofunctor of  $\omega\text{-Cat}$ . Actually, up to isomorphism, all the autoequivalences of  $\omega\text{-Cat}$  are of the form  $D_S$ . We will sometimes refer to these autoequivalences as *dualities*.

Several special cases play an important role in the theory of  $\omega$ -Cat:

- If  $S = \mathbb{N}^*$ , then  $D_{\mathbb{N}^*}$  is denoted by  $D_o$  and is called the *total dual*. We simply write  $C^o$  for the total dual of an  $\omega$ -category  $C$ .
- If  $S = 2\mathbb{N} + 1$  is the set of odd integers, then  $D_{2\mathbb{N}+1}$  is denoted by  $D_{op}$  and is called the *odd dual*. We simply write  $C^{op}$  for the odd dual of an  $\omega$ -category  $C$ .
- If  $S = 2\mathbb{N}^*$  is the set of positive even integers, then  $D_{2\mathbb{N}^*}$  is denoted by  $D_{co}$  and is called the *even dual*. We simply write  $C^{co}$  for the even dual of an  $\omega$ -category  $C$ .
- If  $S = \{1\}$ , then  $D_{\{1\}}$  is denoted by  $D_t$  and is called the *transpose*. We simply write  $C^t$  for the transpose of  $C$ . This coincide with the transpose of  $C$  in the sense of 1.2 when  $C$  is considered as a category enriched over  $\omega$ -Cat endowed with the cartesian product.

By composing all these special dualities, we get a group of eight dualities. In particular, if  $C$  is an  $\omega$ -category, we get seven other  $\omega$ -categories

$$C^o, \quad C^{op}, \quad C^{co}, \quad C^t, \quad C^{to} = (C^o)^t, \quad C^{top} = (C^{op})^t, \quad C^{cot} = (C^{co})^t.$$

Note that this group of dualities is isomorphic to  $(\mathbb{Z}/2\mathbb{Z})^3$ , a natural basis (as a  $\mathbb{Z}/2\mathbb{Z}$ -module) being given by  $D_{op}$ ,  $D_{co}$  and  $D_t$ .

We now recall the compatibilities of the dualities of  $\omega$ -Cat with the Gray tensor product.

**Proposition 2.22.** — *Let  $A$  and  $B$  be two  $\omega$ -categories. There are canonical isomorphisms*

$$(A \otimes B)^{op} \simeq B^{op} \otimes A^{op}, \quad (A \otimes B)^{co} \simeq B^{co} \otimes A^{co}, \quad (A \otimes B)^o \simeq A^o \otimes B^o,$$

*natural in  $A$  and  $B$ . In other words, the functors*

$$D_{co}, D_{op}: \omega\text{-Cat} \rightarrow \omega\text{-Cat}$$

*are anti-monoidal and the functor*

$$D_o: \omega\text{-Cat} \rightarrow \omega\text{-Cat}$$

*is monoidal,  $\omega$ -Cat being endowed with the Gray tensor product.*

*Proof.* — See for instance [4, Proposition A.22]. □

**Remark 2.23.** — Besides the trivial duality,  $D_{op}$ ,  $D_{co}$  and  $D_o$  are the only dualities of  $\omega$ -Cat that are either monoidal or anti-monoidal.

**Remark 2.24.** — It follows from the previous proposition that if  $A$  and  $B$  are two  $\omega$ -categories, then we have natural isomorphisms

$$\begin{aligned} \underline{\text{Hom}}_{\text{oplax}}(A, B)^{op} &\simeq \underline{\text{Hom}}_{\text{lax}}(A^{op}, B^{op}), \\ \underline{\text{Hom}}_{\text{oplax}}(A, B)^{co} &\simeq \underline{\text{Hom}}_{\text{lax}}(A^{co}, B^{co}), \\ \underline{\text{Hom}}_{\text{oplax}}(A, B)^o &\simeq \underline{\text{Hom}}_{\text{oplax}}(A^o, B^o). \end{aligned}$$

**2.25.** — Let  $\mathbb{C}$  be a Gray  $\omega$ -category. Using the previous proposition, from  $\mathbb{C}$ , we can get two skew Gray  $\omega$ -categories  $(D_{\text{op}})_*(\mathbb{C})$  and  $(D_{\text{co}})_*(\mathbb{C})$ , and one Gray  $\omega$ -category  $(D_{\text{o}})_*(\mathbb{C})$ , obtained by applying these dualities Hom-wise (see 1.4 for the notation). Note that in these new Gray or skew Gray  $\omega$ -categories, the 1-cells are never reversed and in some sense there is a shift of the reversed dimensions by 1. With this in mind, we set, with the notation of 1.2,

$$\mathbb{C}^{\text{op}} = ((D_{\text{co}})_*(\mathbb{C}))^{\text{t}}, \quad \mathbb{C}^{\text{co}} = (D_{\text{op}})_*(\mathbb{C}), \quad \mathbb{C}^{\text{o}} = ((D_{\text{o}})_*(\mathbb{C}))^{\text{t}}.$$

Then  $\mathbb{C}^{\text{op}}$  is a Gray  $\omega$ -category, and  $\mathbb{C}^{\text{co}}$  and  $\mathbb{C}^{\text{o}}$  are skew Gray  $\omega$ -categories. We also set

$$\mathbb{C}^{\text{top}} = (\mathbb{C}^{\text{op}})^{\text{t}}, \quad \mathbb{C}^{\text{cot}} = (\mathbb{C}^{\text{co}})^{\text{t}}, \quad \mathbb{C}^{\text{to}} = (\mathbb{C}^{\text{o}})^{\text{t}}.$$

To sum up, from a Gray  $\omega$ -category  $\mathbb{C}$ , we get three other Gray  $\omega$ -categories

$$\mathbb{C}^{\text{op}}, \quad \mathbb{C}^{\text{cot}}, \quad \mathbb{C}^{\text{to}}$$

and four skew Gray  $\omega$ -categories

$$\mathbb{C}^{\text{t}}, \quad \mathbb{C}^{\text{top}}, \quad \mathbb{C}^{\text{co}}, \quad \mathbb{C}^{\text{o}}.$$

No other duality of  $\omega$ -Cat produces a Gray or a skew Gray  $\omega$ -category.

**2.26.** — Using the previous paragraph, one can interpret the dualities  $D_{\text{co}}$ ,  $D_{\text{op}}$  and  $D_{\text{o}}$  of  $\omega$ -categories as Gray  $\omega$ -functors. More precisely, one can check using 2.24 that these dualities induce isomorphisms of Gray  $\omega$ -categories

$$\begin{aligned} D_{\text{op}} &: (\omega\text{-Cat}_{\text{lax}})^{\text{co}} \rightarrow \omega\text{-Cat}_{\text{oplax}}, \\ D_{\text{co}} &: (\omega\text{-Cat}_{\text{lax}})^{\text{top}} \rightarrow \omega\text{-Cat}_{\text{oplax}}, \\ D_{\text{o}} &: (\omega\text{-Cat}_{\text{oplax}})^{\text{to}} \rightarrow \omega\text{-Cat}_{\text{oplax}}. \end{aligned}$$

Dually, we have isomorphisms of skew Gray  $\omega$ -categories

$$\begin{aligned} D'_{\text{op}} &: (\omega\text{-Cat}_{\text{oplax}})^{\text{co}} \rightarrow \omega\text{-Cat}_{\text{lax}}, \\ D'_{\text{co}} &: (\omega\text{-Cat}_{\text{oplax}})^{\text{top}} \rightarrow \omega\text{-Cat}_{\text{lax}}, \\ D'_{\text{o}} &: (\omega\text{-Cat}_{\text{lax}})^{\text{to}} \rightarrow \omega\text{-Cat}_{\text{lax}}. \end{aligned}$$

### 3. Comma $\omega$ -categories

**3.1.** — Consider a diagram

$$A \xrightarrow{f} C \xleftarrow{g} B$$

in  $\omega\text{-Cat}$ . The comma  $\omega$ -category  $A \downarrow_C B$ , also denoted by  $f \downarrow g$ , is the universal  $\omega$ -category endowed with a 2-square

$$\begin{array}{ccc} & A \downarrow_C B & \\ p_1 \swarrow & & \searrow p_2 \\ A & \xRightarrow{\gamma} & B \\ f \searrow & & \swarrow g \\ & C & \end{array}$$

in  $\omega\text{-Cat}_{\text{oplax}}$ , that is, where  $p_1$  and  $p_2$  are  $\omega$ -functors and  $\gamma$  is an *oplax* transformation. This means that if  $T$  is an  $\omega$ -category endowed with a similar 2-square

$$\begin{array}{ccc} & T & \\ a \swarrow & & \searrow b \\ A & \xRightarrow{\lambda} & B \\ f \searrow & & \swarrow g \\ & C & \end{array},$$

then there exists a unique  $\omega$ -functor  $h: T \rightarrow A \downarrow_C B$  that factors the diagram in the sense that

$$p_1 h = a, \quad p_2 h = b \quad \text{and} \quad \gamma *_0 h = \lambda.$$

By 2.8, and with its notation, the data of such a 2-square is equivalent to the data of an  $\omega$ -functor from  $T$  to the limit of the diagram

$$\begin{array}{ccccc} A & & \Gamma C & & B \\ f \searrow & & \swarrow s & \searrow t & \swarrow g \\ & C & & C & \end{array}.$$

This shows that we have

$$A \downarrow_C B = A \times_C \Gamma C \times_C B.$$

The canonical projections  $p_1$  and  $p_2$  are the obvious projections on  $A$  and  $B$ , and the 2-cell  $\gamma: fp_1 \Rightarrow gp_2$  corresponds to the projection

$$\gamma: A \downarrow_C B \rightarrow \Gamma C.$$

**Example 3.2.** — The slice  $\omega$ -categories are particular cases of comma  $\omega$ -categories. Indeed, if  $C$  is an  $\omega$ -category and  $c$  is an object of  $C$ , then the comma construction  $c \downarrow C$  of the diagram

$$D_0 \xrightarrow{c} C \xleftarrow{1_C} C$$

is canonically isomorphic to the slice  $\omega$ -category  $c \setminus C$  described in [4, Chapter 9] (see [3, Proposition 7.1] for a proof). More generally, if  $v: B \rightarrow C$  is an  $\omega$ -functor, then we have

$$c \setminus B = c \downarrow v,$$

where  $c \setminus B$  is the relative slice defined by the pullback

$$\begin{array}{ccc} c \setminus B & \longrightarrow & c \setminus C \\ \downarrow & \lrcorner & \downarrow U \\ B & \xrightarrow{v} & C \end{array} ,$$

with  $U$  denoting the forgetful  $\omega$ -functor.

Similarly, we have

$$C/c = C \downarrow c$$

and, more generally, if  $u: A \rightarrow C$  is an  $\omega$ -functor,

$$A/c = u \downarrow c .$$

**3.3.** — The comma construction  $A \downarrow_C B$  is functorial in  $A$  and  $B$ . Indeed, if

$$\begin{array}{ccccc} A & & & & B \\ & \searrow f & & \nearrow g & \\ & & C & & \\ & \nearrow f' & & \searrow g' & \\ A' & & & & B' \end{array} \begin{array}{c} \\ \alpha \\ \\ \beta \\ \\ \\ \end{array} \begin{array}{c} \\ u \\ \\ v \\ \\ \\ \end{array}$$

is a diagram in  $\omega\text{-Cat}_{\text{oplax}}$ , then we get an  $\omega$ -functor

$$(f, \alpha) \downarrow (\beta, g): A \downarrow_C B \rightarrow A' \downarrow_C B'$$

by applying the universal property of  $A' \downarrow_C B'$  to the 2-square obtained by composing the diagram

$$\begin{array}{ccccc} & & A \downarrow_C B & & \\ & \swarrow p_1 & \xrightarrow{\gamma} & \searrow p_2 & \\ A & & & & B \\ & \searrow f & & \nearrow g & \\ & & C & & \\ & \nearrow f' & & \searrow g' & \\ A' & & & & B' \end{array} \begin{array}{c} \\ \alpha \\ \\ \beta \\ \\ \\ \end{array} \begin{array}{c} \\ u \\ \\ v \\ \\ \\ \end{array}$$

Therefore, the comma construction defines a functor from the obvious category whose objects are the diagrams

$$A \xrightarrow{f} C \xleftarrow{g} B$$

and whose morphisms are diagrams

$$\begin{array}{ccccc} A & & & & B \\ & \searrow f & & \nearrow g & \\ & & C & & \\ & \nearrow f' & & \searrow g' & \\ A' & & & & B' \end{array} \begin{array}{c} \\ \alpha \\ \\ \beta \\ \\ \\ \end{array} \begin{array}{c} \\ u \\ \\ v \\ \\ \\ \end{array}$$

in  $\omega\text{-Cat}_{\text{oplax}}$  to the category  $\omega\text{-Cat}$ .

In [3], the first-named author and Maltiniotis proved that the comma construction can be promoted to a sesquifunctor. The main goal of the present paper is to express and prove the full functorialities of the comma construction, with respect to the higher structure of the Gray  $\omega$ -category  $\omega\text{-Cat}_{\text{oplax}}$ . To do so, one ingredient will be the  $\omega$ -categorical universal property of the comma construction that we will now describe.

**3.4.** — Let

$$A \xrightarrow{f} C \xleftarrow{g} B$$

be as before and consider the universal 2-square

$$\begin{array}{ccc} & A \downarrow_C B & \\ p_1 \swarrow & & \searrow p_2 \\ A & \xrightarrow{\gamma} & B \\ f \searrow & & \swarrow g \\ & C & \end{array} .$$

For every  $\omega$ -category  $T$ , we have a canonical  $\omega$ -functor

$$\begin{array}{c} \underline{\text{Hom}}_{\text{oplax}}(T, A \downarrow_C B) \\ \downarrow \\ \underline{\text{Hom}}_{\text{oplax}}(T, A) \times_{\underline{\text{Hom}}_{\text{oplax}}(T, C)} \underline{\text{Hom}}_{\text{oplax}}(T, \Gamma C) \times_{\underline{\text{Hom}}_{\text{oplax}}(T, C)} \underline{\text{Hom}}_{\text{oplax}}(T, B) \quad , \end{array}$$

induced by the projections  $p_1$ ,  $\gamma$  and  $p_2$ , which we can identify with an  $\omega$ -functor

$$\underline{\text{Hom}}_{\text{oplax}}(T, A \downarrow_C B) \longrightarrow \underline{\text{Hom}}_{\text{oplax}}(T, A) \downarrow_{\underline{\text{Hom}}_{\text{oplax}}(T, C)} \underline{\text{Hom}}_{\text{oplax}}(T, B)$$

using the canonical isomorphism  $\underline{\text{Hom}}_{\text{oplax}}(T, \Gamma C) \simeq \Gamma \underline{\text{Hom}}_{\text{oplax}}(T, C)$  of 2.8. Since the functor  $\underline{\text{Hom}}_{\text{oplax}}(T, -): \omega\text{-Cat} \rightarrow \omega\text{-Cat}$  is a right adjoint, it commutes with fibred products and we get the following result:

**Proposition 3.5 (Higher universal property of the comma construction)**

If  $A \xrightarrow{f} C \xleftarrow{g} B$  is a diagram in  $\omega\text{-Cat}$ , then for any  $\omega$ -category  $T$  the canonical morphism

$$\underline{\text{Hom}}_{\text{oplax}}(T, A \downarrow_C B) \xrightarrow{\sim} \underline{\text{Hom}}_{\text{oplax}}(T, A) \downarrow_{\underline{\text{Hom}}_{\text{oplax}}(T, C)} \underline{\text{Hom}}_{\text{oplax}}(T, B)$$

is an isomorphism.

The enriched description of the  $\omega$ -category of cylinders (see 2.12) leads to an analogous description for the comma  $\omega$ -category:

**3.6.** — If  $A \xrightarrow{f} C \xleftarrow{g} B$  is a diagram in  $\omega\text{-Cat}$ , then the  $\omega$ -category  $A \downarrow_C B$  can be described (up to isomorphism) as a category enriched in  $\omega$ -categories in the following way:

- The objects of  $A \downarrow_C B$  are triples  $(a, l: fa \rightarrow gb, b)$ , where  $a$  is an object of  $A$ ,  $b$  an object of  $B$  and  $l$  a 1-cell of  $C$ .
- If  $(a, l: fa \rightarrow gb, b)$  and  $(a', l': fa' \rightarrow gb', b')$  are two objects of  $A \downarrow_C B$ , then

$$\underline{\mathbf{Hom}}_{A \downarrow_C B}((a, l, b), (a', l', b')) \\ = \underline{\mathbf{Hom}}_A(a, a') \times_{\underline{\mathbf{Hom}}_C(fa, gb')} \Gamma \underline{\mathbf{Hom}}_C(fa, gb') \times_{\underline{\mathbf{Hom}}_C(fa, gb')} \underline{\mathbf{Hom}}_B(b, b'),$$

where this iterated fiber product denotes the limit of the diagram

$$\begin{array}{ccccc} \underline{\mathbf{Hom}}_A(a, a') & & \Gamma \underline{\mathbf{Hom}}_C(fa, gb') & & \underline{\mathbf{Hom}}_B(b, b') \\ & \searrow^{l' *_0 f(-)} & \swarrow_{\mathfrak{s}} & \searrow_{\mathfrak{t}} & \swarrow_{g(-) *_0 l} \\ & & \underline{\mathbf{Hom}}_C(fa, gb') & & \underline{\mathbf{Hom}}_C(fa, gb') \end{array} .$$

This  $\omega$ -category is actually itself a comma  $\omega$ -category, namely

$$\underline{\mathbf{Hom}}_A(a, a') \downarrow_{\underline{\mathbf{Hom}}_C(fa, gb')} \underline{\mathbf{Hom}}_B(b, b').$$

Concretely, a  $k$ -cell in this  $\mathbf{Hom}$  is a triple  $(u, \alpha, v)$  in

$$\underline{\mathbf{Hom}}_A(a, a')_k \times \Gamma \underline{\mathbf{Hom}}_C(fa, gb')_k \times \underline{\mathbf{Hom}}_B(b, b')_k$$

such that

$$\mathfrak{s}(\alpha) = l' *_0 f(u) \quad \text{and} \quad \mathfrak{t}(\alpha) = g(v) *_0 l.$$

- If  $(a, l, b), (a', l', b'), (a'', l'', b'')$  are three objects of  $A \downarrow_C B$ , the composition  $\omega$ -functor

$$\begin{array}{c} \underline{\mathbf{Hom}}_{A \downarrow_C B}((a', l', b'), (a'', l'', b'')) \times \underline{\mathbf{Hom}}_{A \downarrow_C B}((a, l, b), (a', l', b')) \\ \downarrow \\ \underline{\mathbf{Hom}}_{A \downarrow_C B}((a, l, b), (a'', l'', b'')) \end{array}$$

is given by

$$((u', \alpha', v'), (u, \alpha, v)) \mapsto (u' *_0 u, (g(v') *_l \alpha) *_c (\alpha' *_r f(u)), v' *_0 v).$$

- If  $(a, l, b)$  is an object of  $A \downarrow_C B$ , its unit is the triple  $(1_a, \mathbb{1}_l, 1_b)$ .

**3.7.** — The comma construction we studied in this section is the *oplax* comma construction. Similarly, one can define a *lax comma construction* by replacing the oplax transformation in the 2-square of the universal property of the oplax comma construction by a lax transformation. If

$$A \xrightarrow{f} C \xleftarrow{g} B$$

is a diagram in  $\omega\text{-Cat}$ , we will denote by  $A \downarrow'_C B$ , or  $f \downarrow'_C g$ , the lax comma construction of  $f$  and  $g$ . Explicitly, we have

$$A \downarrow'_C B = A \times_C \Gamma' C \times_C B,$$

where  $\Gamma' C = \underline{\mathbf{Hom}}_{\text{oplax}}(\mathbb{D}_1, C)$ .

The lax comma construction can also be defined by duality from the oplax version. Indeed, there are natural isomorphisms

$$(A \downarrow_C B)^{\text{op}} \simeq B^{\text{op}} \downarrow'_{C^{\text{op}}} A^{\text{op}} \quad \text{and} \quad (A \downarrow_C B)^{\text{co}} \simeq A^{\text{co}} \downarrow'_{C^{\text{co}}} B^{\text{co}}.$$

In particular, we have

$$(A \downarrow_C B)^{\circ} \simeq B^{\circ} \downarrow_{C^{\circ}} A^{\circ} \quad \text{and} \quad (A \downarrow'_C B)^{\circ} \simeq B^{\circ} \downarrow'_{C^{\circ}} A^{\circ}.$$

In this text, we will mainly deal with the oplax version of the comma construction and therefore drop the adjective ‘‘oplax’’.

#### 4. Slices of Gray $\omega$ -categories

The purpose of this section is to define, for  $\mathbb{C}$  a Gray  $\omega$ -category and  $c$  an object of  $\mathbb{C}$ , a slice Gray  $\omega$ -category  $\mathbb{C}/c$ .

The description of the comma construction of 3.6 gives in particular an enriched description for the slices of  $\omega$ -categories. We will see that this description can be adapted to Gray  $\omega$ -categories. The definition will involve the  $\omega$ -category

$$\Gamma(\underline{\text{Hom}}_{\mathbb{C}}(d, c)) = \underline{\text{Hom}}_{\text{lax}}(D_1, \underline{\text{Hom}}_{\mathbb{C}}(d, c)),$$

where  $d$  is another object of  $\mathbb{C}$ , and we start the section by an analysis of the structure of this  $\omega$ -category.

**4.1.** — Let  $\mathbb{C}$  be a Gray  $\omega$ -category. For every object  $c$  of  $\mathbb{C}$ , by composing the two skew Gray  $\omega$ -functors

$$\mathbb{C}^{\text{t}} \xrightarrow{\underline{\text{Hom}}_{\mathbb{C}}(-, c)} \omega\text{-Cat}_{\text{lax}} \xrightarrow{\Gamma} \omega\text{-Cat}_{\text{lax}},$$

where

$$\Gamma = \underline{\text{Hom}}_{\text{lax}}(D_1, -),$$

we get a skew Gray  $\omega$ -functor

$$\Gamma(\underline{\text{Hom}}_{\mathbb{C}}(-, c)): \mathbb{C}^{\text{t}} \rightarrow \omega\text{-Cat}_{\text{lax}}.$$

By Proposition 1.10, this means that  $\Gamma(\underline{\text{Hom}}_{\mathbb{C}}(-, c))$  is a right  $\mathbb{C}$ -module in the sense of 1.9.

**4.2.** — Let  $\mathbb{C}$  be a Gray  $\omega$ -category and let  $a, b$  and  $c$  be three objects of  $\mathbb{C}$ . The structure of right  $\mathbb{C}$ -module of the previous paragraph defines an  $\omega$ -functor

$$*_r: \Gamma \underline{\text{Hom}}_{\mathbb{C}}(b, c) \otimes \underline{\text{Hom}}_{\mathbb{C}}(a, b) \rightarrow \Gamma \underline{\text{Hom}}_{\mathbb{C}}(a, c).$$

Moreover, the axioms of modules give that, if  $a, b, c$  and  $d$  are four objects of  $\mathbb{C}$ , then the diagrams

$$\begin{array}{ccc} \Gamma \underline{\text{Hom}}_{\mathbb{C}}(c, d) \otimes \underline{\text{Hom}}_{\mathbb{C}}(b, c) \otimes \underline{\text{Hom}}_{\mathbb{C}}(a, b) & \xrightarrow{\Gamma \underline{\text{Hom}}_{\mathbb{C}}(c, d) \otimes *_0} & \Gamma \underline{\text{Hom}}_{\mathbb{C}}(c, d) \otimes \underline{\text{Hom}}_{\mathbb{C}}(a, c) \\ \downarrow *_r \otimes \underline{\text{Hom}}_{\mathbb{C}}(a, b) & & \downarrow *_r \\ \Gamma \underline{\text{Hom}}_{\mathbb{C}}(b, d) \otimes \underline{\text{Hom}}_{\mathbb{C}}(a, b) & \xrightarrow{*_r} & \Gamma \underline{\text{Hom}}_{\mathbb{C}}(a, d) \end{array}$$

and

$$\begin{array}{ccc} \Gamma \underline{\text{Hom}}_{\mathbb{C}}(a, b) & \xrightarrow{\Gamma \underline{\text{Hom}}_{\mathbb{C}}(a, b) \otimes 1_a} & \Gamma \underline{\text{Hom}}_{\mathbb{C}}(a, b) \otimes \underline{\text{Hom}}_{\mathbb{C}}(a, a) \\ & \searrow = & \downarrow *_r \\ & & \Gamma \underline{\text{Hom}}_{\mathbb{C}}(a, b) \end{array}$$

commute.

**4.3.** — We saw in 2.9 that, if  $C$  is an  $\omega$ -category, then we have  $\omega$ -functors

$$\mathfrak{s}, \mathfrak{t}: \Gamma C \rightarrow C, \quad \mathfrak{k}: C \rightarrow \Gamma C \quad \text{and} \quad *_c: \Gamma C \times_C \Gamma C \rightarrow \Gamma C$$

that define a structure of category internal to  $\omega$ -categories. All the operations of this structure are natural in  $C$ . This means that this structure of internal category to  $\omega\text{-Cat}$  extends to a structure of internal category to the category of skew Gray  $\omega$ -functors from  $\omega\text{-Cat}_{\text{lax}}$  to itself and strict transformations between them. More precisely, the skew Gray  $\omega$ -functor  $\Gamma: \omega\text{-Cat}_{\text{lax}} \rightarrow \omega\text{-Cat}_{\text{lax}}$  is the object of morphisms of a category internal to the category of skew Gray  $\omega$ -functors from  $\omega\text{-Cat}_{\text{lax}}$  to itself, the object of objects being the identity skew Gray  $\omega$ -functor.

**4.4.** — Let  $\mathbb{C}$  be a Gray  $\omega$ -category and let  $c$  be an object of  $\mathbb{C}$ . By precomposing the internal category of the previous paragraph with the skew Gray  $\omega$ -functor

$$\underline{\text{Hom}}_{\mathbb{C}}(-, c): \mathbb{C}^{\text{t}} \rightarrow \omega\text{-Cat}_{\text{lax}},$$

we get that

$$\Gamma(\underline{\text{Hom}}_{\mathbb{C}}(-, c)): \mathbb{C}^{\text{t}} \rightarrow \omega\text{-Cat}_{\text{lax}}$$

is the object of morphisms of a category internal to the category of skew Gray  $\omega$ -functors from  $\mathbb{C}^{\text{t}}$  to  $\omega\text{-Cat}_{\text{lax}}$ , with object of objects  $\underline{\text{Hom}}_{\mathbb{C}}(-, c)$  and structure maps

$$\mathfrak{s}, \mathfrak{t}: \Gamma \underline{\text{Hom}}_{\mathbb{C}}(-, c) \Rightarrow \underline{\text{Hom}}_{\mathbb{C}}(-, c), \quad \mathfrak{k}: \underline{\text{Hom}}_{\mathbb{C}}(-, c) \Rightarrow \Gamma \underline{\text{Hom}}_{\mathbb{C}}(-, c)$$

and

$$*_c: \Gamma \underline{\text{Hom}}_{\mathbb{C}}(-, c) \times_{\underline{\text{Hom}}_{\mathbb{C}}(-, c)} \Gamma \underline{\text{Hom}}_{\mathbb{C}}(-, c) \Rightarrow \Gamma \underline{\text{Hom}}_{\mathbb{C}}(-, c).$$

By Proposition 1.10, this means that  $\Gamma(\underline{\text{Hom}}_{\mathbb{C}}(-, c))$  is the object of morphisms of a category internal to the category of right  $\mathbb{C}$ -modules and the four above structure maps correspond to morphisms of right  $\mathbb{C}$ -modules.

**4.5.** — Let  $\mathbb{C}$  be a Gray  $\omega$ -category and let  $a, b$  and  $c$  be three objects of  $\mathbb{C}$ . The fact that the structure maps  $\mathfrak{s}, \mathfrak{t}, \mathfrak{k}$  and  $*_c$  of the previous paragraph correspond to morphisms of right  $\mathbb{C}$ -modules precisely means that the squares

$$\begin{array}{ccc} \Gamma \underline{\mathbf{Hom}}_{\mathbb{C}}(b, c) \otimes \underline{\mathbf{Hom}}_{\mathbb{C}}(a, b) & \xrightarrow{*_r} & \Gamma \underline{\mathbf{Hom}}_{\mathbb{C}}(a, c) \\ \mathfrak{e} \otimes \underline{\mathbf{Hom}}_{\mathbb{C}}(a, b) \downarrow & & \downarrow \mathfrak{e} \\ \underline{\mathbf{Hom}}_{\mathbb{C}}(b, c) \otimes \underline{\mathbf{Hom}}_{\mathbb{C}}(a, b) & \xrightarrow[*_0]{} & \underline{\mathbf{Hom}}_{\mathbb{C}}(a, c) \end{array} \quad ,$$

for  $\mathfrak{e}$  being  $\mathfrak{s}$  or  $\mathfrak{t}$ ,

$$\begin{array}{ccc} \Gamma \underline{\mathbf{Hom}}_{\mathbb{C}}(b, c) \otimes \underline{\mathbf{Hom}}_{\mathbb{C}}(a, b) & \xrightarrow{*_r} & \Gamma \underline{\mathbf{Hom}}_{\mathbb{C}}(a, c) \\ \mathfrak{k} \otimes \underline{\mathbf{Hom}}_{\mathbb{C}}(a, b) \uparrow & & \uparrow \mathfrak{k} \\ \underline{\mathbf{Hom}}_{\mathbb{C}}(b, c) \otimes \underline{\mathbf{Hom}}_{\mathbb{C}}(a, b) & \xrightarrow[*_0]{} & \underline{\mathbf{Hom}}_{\mathbb{C}}(a, c) \end{array}$$

and

$$\begin{array}{ccc} (\Gamma \underline{\mathbf{Hom}}_{\mathbb{C}}(b, c) \times_{\underline{\mathbf{Hom}}_{\mathbb{C}}(b, c)} \Gamma \underline{\mathbf{Hom}}_{\mathbb{C}}(b, c)) \otimes \underline{\mathbf{Hom}}_{\mathbb{C}}(a, b) & \xrightarrow[*_c \otimes 1]{} & \Gamma \underline{\mathbf{Hom}}_{\mathbb{C}}(b, c) \otimes \underline{\mathbf{Hom}}_{\mathbb{C}}(a, b) \\ \downarrow & & \downarrow *_r \\ \Gamma \underline{\mathbf{Hom}}_{\mathbb{C}}(a, c) \times_{\underline{\mathbf{Hom}}_{\mathbb{C}}(a, c)} \Gamma \underline{\mathbf{Hom}}_{\mathbb{C}}(a, c) & \xrightarrow[*_c]{} & \Gamma \underline{\mathbf{Hom}}_{\mathbb{C}}(a, c) \end{array} \quad ,$$

where the left vertical arrow is the composite

$$\begin{array}{ccc} (\Gamma \underline{\mathbf{Hom}}_{\mathbb{C}}(b, c) \times_{\underline{\mathbf{Hom}}_{\mathbb{C}}(b, c)} \Gamma \underline{\mathbf{Hom}}_{\mathbb{C}}(b, c)) \otimes \underline{\mathbf{Hom}}_{\mathbb{C}}(a, b) & & \\ \text{can} \downarrow & & \\ (\Gamma \underline{\mathbf{Hom}}_{\mathbb{C}}(b, c) \otimes \underline{\mathbf{Hom}}_{\mathbb{C}}(a, b)) \times_{\underline{\mathbf{Hom}}_{\mathbb{C}}(b, c) \otimes \underline{\mathbf{Hom}}_{\mathbb{C}}(a, b)} (\Gamma \underline{\mathbf{Hom}}_{\mathbb{C}}(b, c) \otimes \underline{\mathbf{Hom}}_{\mathbb{C}}(a, b)) & & \\ *_r \times *_0 \times *_r \downarrow & & \\ \Gamma \underline{\mathbf{Hom}}_{\mathbb{C}}(a, c) \times_{\underline{\mathbf{Hom}}_{\mathbb{C}}(a, c)} \Gamma \underline{\mathbf{Hom}}_{\mathbb{C}}(a, c) & , & \end{array}$$

commute.

**Remark 4.6.** — Note that if  $a, b$  and  $c$  are three objects of a Gray  $\omega$ -category  $\mathbb{C}$ , there is no natural  $\omega$ -functor

$$\underline{\mathbf{Hom}}_{\mathbb{C}}(b, c) \otimes \Gamma \underline{\mathbf{Hom}}_{\mathbb{C}}(a, b) \rightarrow \Gamma \underline{\mathbf{Hom}}_{\mathbb{C}}(a, c) \quad ,$$

and in particular, there is no natural structure of left  $\mathbb{C}$ -module on  $\Gamma \underline{\mathbf{Hom}}_{\mathbb{C}}(a, -)$ . What is true is that  $\Gamma' \underline{\mathbf{Hom}}_{\mathbb{C}}(a, -)$ , where  $\Gamma'(C) = \underline{\mathbf{Hom}}_{\text{oplax}}(D_1, C)$ , is naturally a left  $\mathbb{C}$ -module

We can now define slice Gray  $\omega$ -categories.

**4.7.** — Let  $\mathbb{C}$  be a Gray  $\omega$ -category and let  $c$  be an object of  $\mathbb{C}$ . We define the *slice Gray  $\omega$ -category*  $\mathbb{C}/_c$  in the following way:

– The objects of  $\mathbb{C}/_c$  are pairs  $(d, f: d \rightarrow c)$ , where  $d$  is an object of  $\mathbb{C}$  and  $f$  a 1-cell.

– If  $(d, f: d \rightarrow c)$  and  $(d', f': d' \rightarrow c)$  are two objects of  $\mathbb{C}/_c$ , we set

$$\begin{aligned} \underline{\mathbf{Hom}}_{\mathbb{C}/_c}((d, f), (d', f')) &= \underline{\mathbf{Hom}}_{\mathbb{C}}(d, d') \times_{\underline{\mathbf{Hom}}_{\mathbb{C}}(d, c)} \Gamma \underline{\mathbf{Hom}}_{\mathbb{C}}(d, c) \times_{\underline{\mathbf{Hom}}_{\mathbb{C}}(d, c)} \{f\} \\ &= \underline{\mathbf{Hom}}_{\mathbb{C}}(d, d') \downarrow_{\underline{\mathbf{Hom}}_{\mathbb{C}}(d, c)} \{f\}. \end{aligned}$$

By definition, a  $k$ -cell in this  $\mathbf{Hom}$  consists of a pair  $(u, \alpha)$ , with  $u$  a  $k$ -cell of  $\underline{\mathbf{Hom}}_{\mathbb{C}}(d, d')$  and  $\alpha$  a  $k$ -cell of  $\Gamma \underline{\mathbf{Hom}}_{\mathbb{C}}(d, c)$  such that

$$\mathfrak{s}(\alpha) = f' *_0 u \quad \text{and} \quad \mathfrak{t}(\alpha) = 1_f.$$

In particular, an object of this  $\mathbf{Hom}$  corresponds to a 2-triangle

$$\begin{array}{ccc} d & \xrightarrow{\quad} & d' \\ & \searrow f & \swarrow f' \\ & & c \end{array} .$$

We will denote by  $U$  and  $\gamma$  the projections

$$\begin{aligned} U: \underline{\mathbf{Hom}}_{\mathbb{C}/_c}((d, f), (d', f')) &\rightarrow \underline{\mathbf{Hom}}_{\mathbb{C}}(d, d') \\ \gamma: \underline{\mathbf{Hom}}_{\mathbb{C}/_c}((d, f), (d', f')) &\rightarrow \Gamma \underline{\mathbf{Hom}}_{\mathbb{C}}(d, c), \end{aligned}$$

so that

$$U(u, \alpha) = u \quad \text{and} \quad \gamma(u, \alpha) = \alpha.$$

– If  $(d, f: d \rightarrow c)$  is an object of  $\mathbb{C}/_c$ , the associated unit

$$D_0 \rightarrow \underline{\mathbf{Hom}}_{\mathbb{C}/_c}((d, f), (d, f))$$

is given by the pair

$$D_0 \xrightarrow{1_d} \underline{\mathbf{Hom}}_{\mathbb{C}}(d, d), \quad D_0 \xrightarrow{f} \underline{\mathbf{Hom}}_{\mathbb{C}}(d, c) \xrightarrow{\mathfrak{k}} \Gamma(\underline{\mathbf{Hom}}_{\mathbb{C}}(d, c)).$$

Concretely, it corresponds to the 2-triangle

$$\begin{array}{ccc} d & \xrightarrow{1_d} & d \\ & \searrow f & \swarrow f \\ & & c \end{array} .$$

In symbols, we have

$$1_{(d, f)} = (1_d, \mathbb{1}_f)$$

(remember that we denote  $\mathfrak{k}(f)$  by  $\mathbb{1}_f$ ).

– Let  $(d, f)$ ,  $(d', f')$  and  $(d'', f'')$  be three objects of  $\mathbb{C}/c$ . We now define the composition  $\omega$ -functor

$$\underline{\mathrm{Hom}}_{\mathbb{C}/c}((d', f'), (d'', f'')) \otimes \underline{\mathrm{Hom}}_{\mathbb{C}/c}((d, f), (d', f')) \rightarrow \underline{\mathrm{Hom}}_{\mathbb{C}/c}((d, f), (d'', f'')) .$$

To define such an  $\omega$ -functor we need to define two  $\omega$ -functors

$$\begin{aligned} \underline{\mathrm{Hom}}_{\mathbb{C}/c}((d', f'), (d'', f'')) \otimes \underline{\mathrm{Hom}}_{\mathbb{C}/c}((d, f), (d', f')) &\rightarrow \underline{\mathrm{Hom}}_{\mathbb{C}}(d, d'') \\ \underline{\mathrm{Hom}}_{\mathbb{C}/c}((d', f'), (d'', f'')) \otimes \underline{\mathrm{Hom}}_{\mathbb{C}/c}((d, f), (d', f')) &\rightarrow \Gamma(\underline{\mathrm{Hom}}_{\mathbb{C}}(d, c)) \end{aligned}$$

compatible with the pullback defining  $\underline{\mathrm{Hom}}_{\mathbb{C}/c}((d, f), (d'', f''))$ . The first one is defined by composing

$$\begin{array}{ccc} \underline{\mathrm{Hom}}_{\mathbb{C}/c}((d', f'), (d'', f'')) \otimes \underline{\mathrm{Hom}}_{\mathbb{C}/c}((d, f), (d', f')) & & \\ \downarrow U \otimes U & & \\ \underline{\mathrm{Hom}}_{\mathbb{C}}(d', d'') \otimes \underline{\mathrm{Hom}}_{\mathbb{C}}(d, d') & \xrightarrow{*_0} & \underline{\mathrm{Hom}}_{\mathbb{C}}(d, d'') \end{array} .$$

The second one is defined by composing

$$\begin{array}{ccc} \underline{\mathrm{Hom}}_{\mathbb{C}/c}((d', f'), (d'', f'')) \otimes \underline{\mathrm{Hom}}_{\mathbb{C}/c}((d, f), (d', f')) & & \\ \downarrow & & \\ \Gamma(\underline{\mathrm{Hom}}_{\mathbb{C}}(d, c)) \times_{\underline{\mathrm{Hom}}_{\mathbb{C}}(d, c)} \Gamma(\underline{\mathrm{Hom}}_{\mathbb{C}}(d, c)) & \xrightarrow{*_c} & \Gamma(\underline{\mathrm{Hom}}_{\mathbb{C}}(d, c)) \end{array} ,$$

where the vertical morphism is induced by the following commutative hexagon

$$\begin{array}{ccccc} & \underline{\mathrm{Hom}}_{\mathbb{C}/c}((d', f'), (d'', f'')) \otimes \underline{\mathrm{Hom}}_{\mathbb{C}/c}((d, f), (d', f')) & & & \\ & \swarrow \pi_2 & & \searrow \gamma \otimes U & \\ \underline{\mathrm{Hom}}_{\mathbb{C}/c}((d, f), (d', f')) & & & & \Gamma(\underline{\mathrm{Hom}}_{\mathbb{C}}(d', c)) \otimes \underline{\mathrm{Hom}}_{\mathbb{C}}(d, d') \\ \downarrow \gamma & & & & \downarrow *_r \\ \Gamma(\underline{\mathrm{Hom}}_{\mathbb{C}}(d, c)) & & & & \Gamma(\underline{\mathrm{Hom}}_{\mathbb{C}}(d, c)) \\ & \searrow s & & \swarrow t & \\ & \underline{\mathrm{Hom}}_{\mathbb{C}}(d, c) & & & \end{array} .$$

The fact that this indeed defines a composition  $\omega$ -functor will be proven below. In symbols, we have

$$(u', \alpha') *_0 (u, \alpha) = (u' *_0 u, \alpha *_c (\alpha' *_r u)) .$$

using first the internal category structure of the  $\omega$ -category of cylinders (see 2.9), then the fact that  $\mathfrak{s}$  is a morphism of right  $\mathbb{C}$ -modules (see the first commutative square of 4.5 for  $\mathfrak{e} = \mathfrak{s}$ ) and finally the associativity of the composition of the Gray  $\omega$ -category  $\mathbb{C}$ . This proves that the left square commutes. As for the right square, we have

$$\mathfrak{t}(\alpha *_c (\alpha' *_r u)) = \mathfrak{t}(\alpha) = 1_f,$$

using again the internal category structure of the  $\omega$ -category of cylinders. This ends the proof that the composition of  $\mathbb{C}/\mathcal{C}$  is well defined.

We now have to check the axioms of Gray  $\omega$ -categories. Let us first prove the associativity. Fix a  $k$ -cell  $(u'', \alpha'')$  of  $\underline{\text{Hom}}_{\mathbb{C}/\mathcal{C}}((d'', f''), (d''', f'''))$ . We have to prove that

$$(u'', \alpha'') *_0 ((u', \alpha') *_0 (u, \alpha)) = \left( u'' *_0 (u' *_0 u), (\alpha *_c (\alpha' *_r u)) *_c (\alpha'' *_r (u' *_0 u)) \right)$$

equals

$$((u'', \alpha'') *_0 (u', \alpha')) *_0 (u, \alpha) = \left( (u'' *_0 u') *_0 u, \alpha *_c [(\alpha' *_c (\alpha'' *_r u')) *_r u] \right).$$

The equality of the first components follows from the associativity of the composition of  $\mathbb{C}$ . As for the second components, we have

$$\begin{aligned} \alpha *_c [(\alpha' *_c (\alpha'' *_r u')) *_r u] &= \alpha *_c [(\alpha' *_r u) *_c ((\alpha'' *_r u') *_r u)] \\ &= \alpha *_c [(\alpha' *_r u) *_c (\alpha'' *_r (u' *_0 u))] \\ &= (\alpha *_c (\alpha' *_r u)) *_c (\alpha'' *_r (u' *_0 u)), \end{aligned}$$

where the first equality follows from the fact that  $*_c$  is a morphism of right  $\mathbb{C}$ -modules (see the last commutative square of 4.5), the second from the fact that  $*_r$  is a right action (see the commutative square of 4.2) and the last from the associativity of the operation  $*_c$  (see 2.9). This ends the proof that the composition of  $\mathbb{C}/\mathcal{C}$  is associative.

Finally, we prove the axioms involving units. For the left unit axiom, we have

$$(u, \alpha) *_0 1_{(d, f)} = (u, \alpha) *_0 (1_d, \mathbb{1}_f) = (u *_0 1_d, \mathbb{1}_f *_c (\alpha *_r 1_d)) = (u, \alpha),$$

where the last equality uses the axiom of units in  $\mathbb{C}$ , the structure of category of 2.9 and the fact that  $*_r$  is a right action (see the commutative triangle of 4.2). Finally, for the right unit axiom, we have

$$1_{(d', f')} *_0 (u, \alpha) = (1_{d'}, \mathbb{1}_{f'}) *_0 (u, \alpha) = (1_{d'} *_0 u, \alpha *_c (\mathbb{1}_{f'} *_r u)) = (u, \alpha),$$

where the last equality uses the axiom of units in  $\mathbb{C}$ , the fact that  $\mathbb{1}$  is a morphism of right  $\mathbb{C}$ -modules (see the second commutative square of 4.5) and the structure of internal category of 2.9.  $\square$

**Remark 4.9.** — The existence of slice Gray  $\omega$ -categories was first conjectured by the first-named author and Maltiniotis [4, conjecture C.24].

**4.10.** — Let  $\mathbb{C}$  be a Gray  $\omega$ -category and let  $c$  be an object of  $\mathbb{C}$ . We have a canonical Gray  $\omega$ -functor

$$U: \mathbb{C}/c \rightarrow \mathbb{C},$$

called the *forgetful Gray  $\omega$ -functor*. It is defined on objects by

$$(d, f) \mapsto d,$$

and, if  $(d, f), (d', f')$  are two objects, on morphisms by the projection

$$U: \underline{\mathbf{Hom}}_{\mathbb{C}/c}((d, f), (d', f')) \rightarrow \underline{\mathbf{Hom}}_{\mathbb{C}}(d, d')$$

(see 4.7).

**Proposition 4.11.** — *Let  $C$  be an  $\omega$ -category and let  $c$  be an object of  $C$ . Then, we have a canonical natural isomorphism*

$$\iota(C)/c \simeq \iota(C/c),$$

*commuting to forgetful morphisms, where  $\iota$  denotes the inclusion functor from  $\omega$ -categories to Gray  $\omega$ -categories.*

*Proof.* — This is true by design of slice Gray  $\omega$ -categories, and more precisely, by the description of slice  $\omega$ -categories that follows from the description of comma  $\omega$ -categories given in 3.6.  $\square$

**Proposition 4.12.** — *Let  $\mathbb{C}$  be a Gray  $\omega$ -category and let  $c$  and  $d$  be two objects of  $\mathbb{C}$ . Then the fiber of the forgetful Gray  $\omega$ -functor  $\mathbb{C}/c \rightarrow \mathbb{C}$  at  $d$  is canonically isomorphic to  $\underline{\mathbf{Hom}}_{\mathbb{C}}(d, c)^\circ$ .*

*Proof.* — Denote by  $U_d$  this fiber. By definition, its objects are 1-cells  $d \rightarrow c$  of  $\mathbb{C}$ , and if  $f$  and  $f'$  are two such objects, we have

$$\underline{\mathbf{Hom}}_{U_d}(f, f') = \{f'\} \times_{\underline{\mathbf{Hom}}_{\mathbb{C}}(d, c)} \Gamma \underline{\mathbf{Hom}}_{\mathbb{C}}(d, c) \times_{\underline{\mathbf{Hom}}_{\mathbb{C}}(d, c)} \{f\} = \{f'\} \downarrow_{\underline{\mathbf{Hom}}_{\mathbb{C}}(d, c)} \{f\}.$$

This means that a  $k$ -cell of this  $\omega$ -category is a  $k$ -cylinder  $\alpha$  in  $\underline{\mathbf{Hom}}_{\mathbb{C}}(d, c)$  such that  $\mathfrak{s}(\alpha) = 1_{f'}$  and  $\mathfrak{t}(\alpha) = 1_f$ . Moreover, the composition  $\omega$ -functor simplifies to

$$\begin{aligned} \underline{\mathbf{Hom}}_{U_d}(f', f'') \otimes \underline{\mathbf{Hom}}_{U_d}(f, f') &\rightarrow \underline{\mathbf{Hom}}_{U_d}(f, f'') \\ (\alpha', \alpha) &\mapsto \alpha' *_c \alpha \end{aligned}$$

(as  $\alpha' *_c (\alpha *_r 1_d) = \alpha' *_c \alpha$ ).

But in general, if  $a$  and  $a'$  are two objects of an  $\omega$ -category  $A$ , we have a canonical isomorphism

$$\{a\} \downarrow_A \{a'\} \xrightarrow{\simeq} \underline{\mathbf{Hom}}_A(a, a')^\circ$$

(see [1, Proposition B.6.2]), sending a  $k$ -cylinder  $\alpha$  in  $A$  to its principal cell  $\alpha_k$  (see 2.8). We thus have

$$\underline{\mathbf{Hom}}_{U_d}(f, f') \simeq \underline{\mathbf{Hom}}_{\underline{\mathbf{Hom}}_{\mathbb{C}}(d, c)}(f', f)^\circ = \underline{\mathbf{Hom}}_{\underline{\mathbf{Hom}}_{\mathbb{C}}(d, c)^\circ}(f, f'),$$

this isomorphism sending a  $k$ -cylinder  $\alpha$  in  $\underline{\mathbf{Hom}}_C(d, c)$  to its principal cell  $\alpha_k$ . Now if  $(\alpha', \alpha)$  is in  $\underline{\mathbf{Hom}}_{U_d}(f', f'')_k \times \underline{\mathbf{Hom}}_{U_d}(f, f')_k$ , then

$$(\alpha' *_c \alpha)_k = \alpha'_k *_0 \alpha_k.$$

This shows that the isomorphism

$$\underline{\mathbf{Hom}}_{U_d}(f, f') \simeq \underline{\mathbf{Hom}}_{\underline{\mathbf{Hom}}_C(d, c)^\circ}(f, f')$$

is compatible with compositions, thereby proving the result.  $\square$

**4.13.** — Let  $C$  be a strict  $\omega$ -category and let  $c$  be an object of  $C$ . If  $D$  is any duality of  $\omega\text{-Cat}$  (see 2.21), then by “conjugating” the slice construction  $C/c$  by  $D$ , one gets another slice construction. If  $D$  does not reverse the 1-cells, we set

$$C/c^D = D(D(C)/c).$$

In the case where  $D$  reverses the 1-cells, this notation would be misleading as  $D(D(C)/c)$  is actually a slice below  $c$  (and not above  $c$ ). In particular, if  $D$  is the total dual, following the notation of [4], we set

$$c \setminus C = (C^\circ/c)^\circ.$$

Now if  $D$  is a general duality reversing the 1-cells, then denoting by  $D'$  the unique duality such that  $D' \circ D$  is the total dual (in particular,  $D'$  does not reverse the 1-cells), one gets

$$D(D(C)/c) = D'((D'(C)^\circ/c)^\circ) = D'(c \setminus D'(C)).$$

Therefore, if  $D$  reverses the 1-cells, we set

$$c \setminus C^{D'} = D(D(C)/c).$$

This means that we only decorate (over or under) slices by dualities that do not reverse the 1-cells.

Let us now apply this to Gray  $\omega$ -categories. If  $\mathbb{C}$  is a Gray  $\omega$ -category and  $c$  is an object of  $\mathbb{C}$ , we can conjugate our Gray slice construction by the three non-trivial dualities of Gray  $\omega$ -categories (see 2.25) and we set

$$c^{\text{co}} \setminus \mathbb{C} = (\mathbb{C}^{\text{op}}/c)^{\text{op}}, \quad c^{\text{top}} \setminus \mathbb{C} = (\mathbb{C}^{\text{cot}}/c)^{\text{cot}}, \quad \mathbb{C}/c^{\text{to}} = (\mathbb{C}^{\text{to}}/c)^{\text{to}}.$$

Note that each of these Gray  $\omega$ -categories admits a forgetful Gray  $\omega$ -functor to  $\mathbb{C}$ .

Similarly, if  $\mathbb{C}$  is a skew Gray  $\omega$ -category and  $c$  is an object of  $\mathbb{C}$ , we set

$$c \setminus \mathbb{C} = (\mathbb{C}^\circ/c)^\circ, \quad \mathbb{C}/c^{\text{co}} = (c \setminus \mathbb{C}^{\text{op}})^{\text{op}}, \quad \mathbb{C}/c^{\text{top}} = (c \setminus \mathbb{C}^{\text{cot}})^{\text{cot}}, \quad c \setminus \mathbb{C}^{\text{to}} = (c \setminus \mathbb{C}^{\text{to}})^{\text{to}}.$$

Each of these skew Gray  $\omega$ -categories admits a forgetful skew Gray  $\omega$ -functor to  $\mathbb{C}$ .

### 5. Gray functorialities of the comma construction

The purpose of this section is to extend the comma construction

$$A \rightarrow C \leftarrow B \quad \mapsto \quad A \downarrow_C B$$

to a Gray  $\omega$ -functor

$$-\downarrow_C - : \omega\text{-Cat}_{\text{oplax}/C} \times \omega\text{-Cat}_{\text{oplax}/C}^{\text{to}} \rightarrow \omega\text{-Cat}_{\text{oplax}},$$

where  $\omega\text{-Cat}_{\text{oplax}/C}$  is the slice Gray  $\omega$ -category obtained by applying Theorem 4.8 to the Gray  $\omega$ -category  $\omega\text{-Cat}_{\text{oplax}}$ , the slice  $\omega\text{-Cat}_{\text{oplax}/C}^{\text{to}}$  is obtained by duality (see 4.13) and the product is the categorical product of Gray  $\omega$ -categories (see 1.3).

**5.1.** — Let us fix  $\omega$ -functors

$$A \xrightarrow{f} C \xleftarrow{g} B \quad \text{and} \quad A' \xrightarrow{f'} C \xleftarrow{g'} B' .$$

To any 2-square

$$\begin{array}{ccc} & T & \\ a \swarrow & & \searrow b \\ A & \xrightarrow{\lambda} & B \\ f \searrow & & \swarrow g \\ & C & \end{array}$$

in  $\omega\text{-Cat}_{\text{oplax}}$ , we are going to associate an  $\omega$ -functor

$$\begin{array}{ccc} K : \underline{\text{Hom}}_{\omega\text{-Cat}_{\text{oplax}/C}}((A, f), (A', f')) \times \underline{\text{Hom}}_{\omega\text{-Cat}_{\text{oplax}/C}^{\text{to}}}((B, g), (B', g')) & & \\ \downarrow & & \\ \underline{\text{Hom}}_{\text{oplax}}(T, A') & \downarrow & \underline{\text{Hom}}_{\text{oplax}}(T, B') \\ & \underline{\text{Hom}}_{\text{oplax}}(T, C) & \end{array} .$$

By definition, we have

$$\begin{aligned} & \underline{\text{Hom}}_{\omega\text{-Cat}_{\text{oplax}/C}}((A, f), (A', f')) \\ &= \underline{\text{Hom}}_{\text{oplax}}(A, A') \times \underline{\text{Hom}}_{\text{oplax}}(A, C) \Gamma \underline{\text{Hom}}_{\text{oplax}}(A, C) \times \underline{\text{Hom}}_{\text{oplax}}(A, C) \{f\} \end{aligned}$$

and, as the duality  $D_{\text{to}}$  consists in applying the total dual  $\text{Hom}$ -wise, we get

$$\begin{aligned} & \underline{\text{Hom}}_{\omega\text{-Cat}_{\text{oplax}/C}^{\text{to}}}((B, g), (B', g')) \\ &= \left( \underline{\text{Hom}}_{\text{oplax}}(B, B')^\circ \times \underline{\text{Hom}}_{\text{oplax}}(B, C)^\circ \Gamma \left( \underline{\text{Hom}}_{\text{oplax}}(B, C)^\circ \times \underline{\text{Hom}}_{\text{oplax}}(B, C)^\circ \{g\} \right)^\circ \right. \\ & \simeq \{g\} \times \underline{\text{Hom}}_{\text{oplax}}(B, C) \Gamma \underline{\text{Hom}}_{\text{oplax}}(B, C) \times \underline{\text{Hom}}_{\text{oplax}}(B, C) \underline{\text{Hom}}_{\text{oplax}}(B, B'), \end{aligned}$$

as

$$(\Gamma(X^\circ))^\circ \simeq \underline{\text{Hom}}_{\text{lax}}(D_1^\circ, X),$$

which is isomorphic to  $\Gamma X$  but in a way that exchanges  $\mathfrak{s}$  and  $\mathfrak{t}$ .

This means that a  $k$ -cell in

$$\underline{\mathbf{Hom}}_{\omega\text{-Cat}_{\text{oplax}/C}}((A, f), (A', f')) \times \underline{\mathbf{Hom}}_{\omega\text{-Cat}_{\text{oplax}/C}^{\text{to}}}((B, g), (B', g'))$$

consists of a 4-tuple

$$(u, \alpha, \beta, v)$$

in

$$\underline{\mathbf{Hom}}_{\text{oplax}}(A, A')_k \times (\Gamma \underline{\mathbf{Hom}}_{\text{oplax}}(A, C))_k \times (\Gamma \underline{\mathbf{Hom}}_{\text{oplax}}(B, C))_k \times \underline{\mathbf{Hom}}_{\text{oplax}}(B, B')_k$$

satisfying

$$\mathfrak{s}(\alpha) = f' *_0 u, \quad \mathfrak{t}(\alpha) = f, \quad \mathfrak{s}(\beta) = g, \quad \mathfrak{t}(\beta) = g' *_0 v.$$

In particular, for  $k = 0$ , we get a diagram

$$\begin{array}{ccccc} A & & & & B \\ & \searrow f & & \swarrow g & \\ & & C & & \\ & \nearrow f' & & \nwarrow g' & \\ A' & & & & B' \end{array} \quad \begin{array}{c} \alpha \nearrow \\ \beta \searrow \end{array} \quad \begin{array}{c} u \downarrow \\ v \downarrow \end{array}.$$

Similarly, a  $k$ -cell of

$$\underline{\mathbf{Hom}}_{\text{oplax}}(T, A') \quad \downarrow \quad \underline{\mathbf{Hom}}_{\text{oplax}}(T, B')$$

$$\underline{\mathbf{Hom}}_{\text{oplax}}(T, C)$$

consists of a triple

$$(a', \lambda', b')$$

in

$$\underline{\mathbf{Hom}}_{\text{oplax}}(T, A')_k \times (\Gamma \underline{\mathbf{Hom}}_{\text{oplax}}(T, C))_k \times \underline{\mathbf{Hom}}_{\text{oplax}}(T, B')_k$$

such that

$$\mathfrak{s}(\lambda') = f' *_0 a' \quad \text{and} \quad \mathfrak{t}(\lambda') = g' *_0 b'.$$

For  $k = 0$ , we get a 2-square

$$\begin{array}{ccc} & T & \\ a' \swarrow & & \searrow b' \\ A' & \xrightarrow{\lambda'} & B' \\ f' \searrow & & \swarrow g' \\ & C & \end{array}.$$

The  $\omega$ -functor  $K$  is defined by  $\omega$ -categorification of the formula giving the total composite of the 2-diagram

that is, by the formula

$$(u, \alpha, \beta, v) \mapsto (u *_0 a, (\beta *_r b) *_c \lambda *_c (\alpha *_r a), v *_0 b),$$

where  $*_c$  denotes the internal composition of cylinders of 2.9 and  $*_r$  the right action of 4.2. This formula is well defined as, first, by 4.2,

$$\mathfrak{s}(\beta *_r b) = \mathfrak{s}(\beta) *_0 b = g *_0 b = \mathfrak{t}(\lambda) \quad \text{and} \quad \mathfrak{t}(\alpha *_r a) = \mathfrak{t}(\alpha) *_0 a = f *_0 a = \mathfrak{s}(\lambda),$$

so that  $\lambda' = (\beta *_r b) *_c \lambda *_c (\alpha *_r a)$  makes sense, and, second, using 2.9 and again 4.2,

$$\mathfrak{s}(\lambda') = \mathfrak{s}(\alpha *_r a) = \mathfrak{s}(\alpha) *_0 a = (f' *_0 u) *_0 a = f' *_0 (u *_0 a),$$

and similarly

$$\mathfrak{t}(\lambda') = g' *_0 (v *_0 b).$$

Moreover, this formula is  $\omega$ -functorial in  $(u, \alpha, \beta, v)$  as it only involves the operations  $*_0$ ,  $*_c$  and  $*_r$ , which are all  $\omega$ -functorial. (We could also have defined the  $\omega$ -functor  $K$  in a more categorical way, as we did for the composition  $*_0$  of Gray slices in 4.7.)

**5.2.** — If we apply the construction of the previous paragraph to the universal 2-square

we get an  $\omega$ -functor

$$\begin{aligned}
-\downarrow_C - : \underline{\mathbf{Hom}}_{\omega\text{-Cat}_{\text{oplax}/C}}((A, f), (A', f')) \times \underline{\mathbf{Hom}}_{\omega\text{-Cat}_{\text{oplax}/C}}^{\text{to}}((B, g), (B', g')) \\
\downarrow \\
\underline{\mathbf{Hom}}_{\text{oplax}}(A \downarrow_C B, A') \quad \underline{\mathbf{Hom}}_{\text{oplax}}(A \downarrow_C B, B') \\
\downarrow \quad \downarrow \\
\underline{\mathbf{Hom}}_{\text{oplax}}(A \downarrow_C B, C) \quad \underline{\mathbf{Hom}}_{\text{oplax}}(A \downarrow_C B, C) \\
\cong \\
\underline{\mathbf{Hom}}_{\text{oplax}}(A \downarrow_C B, A' \downarrow_C B') \quad ,
\end{aligned}$$

where the isomorphism is the higher universal property of the comma construction (see Proposition 3.5). Explicitly, the  $\omega$ -functor  $-\downarrow_C -$  is given by the formula

$$(u, \alpha, \beta, v) \mapsto (u *_0 p_1, (\beta *_r p_2) *_c \gamma *_c (\alpha *_r p_1), v *_0 p_2) .$$

In particular, if  $g: B \rightarrow C$  is an  $\omega$ -functor, we have

$$\begin{aligned}
(-\downarrow_C B)(u, \alpha) &= (-\downarrow_C -)(u, \alpha, \mathbb{1}_g, 1_B) \\
&= (u *_0 p_1, (\mathbb{1}_g *_r p_2) *_c \gamma *_c (\alpha *_c p_1), 1_g *_0 p_2) \\
&= (u *_0 p_1, \gamma *_c (\alpha *_r p_1), p_2) ,
\end{aligned}$$

where the last equality uses the fact that  $\mathbb{1}$  is a morphism of right  $\omega\text{-Cat}_{\text{oplax}}$ -modules (see the second commutative square of 4.5) and the structure of internal category of 2.9, and, similarly, if  $f: A \rightarrow C$  is an  $\omega$ -functor, we have

$$(A \downarrow_C -)(\beta, v) = (p_1, (\beta *_r p_2) *_c \gamma, v *_0 p_2) .$$

**Theorem 5.3.** — *Let  $C$  be an  $\omega$ -category. The comma construction extends, via the construction of the previous paragraph, to a Gray  $\omega$ -functor*

$$-\downarrow_C - : \omega\text{-Cat}_{\text{oplax}/C} \times \omega\text{-Cat}_{\text{oplax}/C}^{\text{to}} \rightarrow \omega\text{-Cat}_{\text{oplax}} .$$

*Proof.* — In this proof, to make our formula more compact, we set

$$\underline{\mathbf{Hom}}_{\text{ol}} = \underline{\mathbf{Hom}}_{\text{oplax}} , \quad \underline{\mathbf{Hom}}_{/C} = \underline{\mathbf{Hom}}_{\omega\text{-Cat}_{\text{oplax}/C}} \quad \text{and} \quad \underline{\mathbf{Hom}}_{/C}^{\text{to}} = \underline{\mathbf{Hom}}_{\omega\text{-Cat}_{\text{oplax}/C}}^{\text{to}} .$$

For the same reason, if  $(T, T \rightarrow C)$  is an  $\omega$ -category over  $C$ , we will denote it simply by  $T$ .

Let us now prove the result. We have to check the compatibility with the unit and the compatibility with the composition. To do so, we will use the same technique as in the proof of Theorem 4.8.

For the unit, we have

$$\begin{aligned}
(-\downarrow_C -)(1_{(A,f)}, 1_{(B,g)}) &= (-\downarrow_C -)(1_A, \mathbb{1}_f, \mathbb{1}_g, 1_B) \\
&= (1_A *_0 p_1, (\mathbb{1}_g *_r p_2) *_c \gamma *_c (\mathbb{1}_f *_r p_1), 1_B *_0 p_2) \\
&= (p_1, \gamma, p_2) \\
&= 1_{A \downarrow_C B} ,
\end{aligned}$$

using the fact that  $\mathbb{1}$  is a morphism of right  $\omega\text{-Cat}_{\text{oplax}}$ -modules (see the second commutative square of 4.5) and the structure of internal category of 2.9.

Let us now check the compatibility with the composition. Consider  $A, A', A'', B, B', B''$  six  $\omega$ -categories over  $C$ . We have to prove that the two canonical  $\omega$ -functors

$$\begin{array}{c} (\underline{\text{Hom}}_{/C}(A', A'') \times \underline{\text{Hom}}_{/C}^{\text{to}}(B', B'')) \otimes (\underline{\text{Hom}}_{/C}(A, A') \times \underline{\text{Hom}}_{/C}^{\text{to}}(B, B')) \\ \downarrow \\ \underline{\text{Hom}}_{\text{ol}}(A \downarrow_C B, A'' \downarrow_C B'') \quad , \end{array}$$

which we will describe below, are equal. Consider

$$(u', \alpha', \beta', u) \quad \text{and} \quad (u, \alpha, \beta, v)$$

cells of

$$\underline{\text{Hom}}_{/C}(A', A'') \times \underline{\text{Hom}}_{/C}^{\text{to}}(B', B'') \quad \text{and} \quad \underline{\text{Hom}}_{/C}(A, A') \times \underline{\text{Hom}}_{/C}^{\text{to}}(B, B')$$

respectively. When these cells are 0-cells, we get a diagram

$$\begin{array}{ccccc} A & & & & B \\ & \searrow f & & & \searrow g \\ u \downarrow & \alpha \nearrow & & & \nearrow \beta \\ A' & \xrightarrow{j'} & C & \xleftarrow{g'} & B' \\ & \searrow \alpha' & & & \searrow \beta' \\ u' \downarrow & \alpha' \nearrow & & & \nearrow \beta' \\ A'' & \xrightarrow{j''} & C & \xleftarrow{g''} & B'' \\ & & & & \searrow v' \\ & & & & B'' \end{array} .$$

Consider first the  $\omega$ -functor  $M$  defined as the composite

$$\begin{array}{c} (\underline{\text{Hom}}_{/C}(A', A'') \times \underline{\text{Hom}}_{/C}^{\text{to}}(B', B'')) \otimes (\underline{\text{Hom}}_{/C}(A, A') \times \underline{\text{Hom}}_{/C}^{\text{to}}(B, B')) \\ \text{can} \downarrow \\ (\underline{\text{Hom}}_{/C}(A', A'') \otimes \underline{\text{Hom}}_{/C}(A, A')) \times (\underline{\text{Hom}}_{/C}^{\text{to}}(B', B'') \otimes \underline{\text{Hom}}_{/C}^{\text{to}}(B, B')) \\ *_{0} \otimes *_{0} \downarrow \\ \underline{\text{Hom}}_{/C}(A, A'') \times \underline{\text{Hom}}_{/C}^{\text{to}}(B, B'') \\ - \downarrow_C - \downarrow \\ \underline{\text{Hom}}_{\text{ol}}(A \downarrow_C B, A'' \downarrow_C B'') \quad . \end{array}$$

We have

$$\begin{aligned}
M((u', \alpha', \beta', v') \otimes (u, \alpha, \beta, v)) & \\
&= (-\downarrow_C -)((u', \alpha') *_{\mathbf{0}} (u, \alpha), (\beta', v') *_{\mathbf{0}} (\beta, v)) \\
&= (-\downarrow_C -)(u' *_{\mathbf{0}} u, \alpha *_{\mathbf{c}} (\alpha' *_{\mathbf{r}} u), (\beta' *_{\mathbf{r}} v) *_{\mathbf{c}} \beta, v' *_{\mathbf{0}} v) \\
&= ((u' *_{\mathbf{0}} u) *_{\mathbf{0}} p_1, \\
&\quad [((\beta' *_{\mathbf{r}} v) *_{\mathbf{c}} \beta) *_{\mathbf{r}} p_2] *_{\mathbf{c}} \gamma *_{\mathbf{c}} [(\alpha *_{\mathbf{c}} (\alpha' *_{\mathbf{r}} u)) *_{\mathbf{r}} p_1], \\
&\quad (v' *_{\mathbf{0}} v) *_{\mathbf{0}} p_2).
\end{aligned}$$

Note that this last formula is an  $\omega$ -categorification of the formula for the total composite of the 2-diagram

Consider now the  $\omega$ -functor  $N$  obtained as the composite

$$\begin{aligned}
&(\underline{\mathbf{Hom}}_{/C}(A', A'') \times \underline{\mathbf{Hom}}_{\mathbf{to}/C}(B', B'')) \otimes (\underline{\mathbf{Hom}}_{/C}(A, A') \times \underline{\mathbf{Hom}}_{\mathbf{to}/C}(B, B')) \\
&\quad \downarrow (-\downarrow_C -) \otimes (-\downarrow_C -) \\
&\underline{\mathbf{Hom}}_{\mathbf{ol}}(A' \downarrow_C B', A'' \downarrow_C B'') \otimes \underline{\mathbf{Hom}}_{\mathbf{ol}}(A \downarrow_C B, A' \downarrow_C B') \\
&\quad \downarrow \circ \\
&\underline{\mathbf{Hom}}_{\mathbf{ol}}(A \downarrow_C B, A'' \downarrow_C B'') \quad .
\end{aligned}$$

Let us compute  $N((u', \alpha', \beta', v') \otimes (u, \alpha, \beta, v))$ . Denote by

the two universal 2-squares involved. By definition, we have

$$\begin{aligned} (-\downarrow_C -)(u', \alpha', \beta', v') &= (u' *_0 p'_1, (\beta' *_r p'_2) *_c \gamma' *_c (\alpha' *_r p'_1), v' *_0 p'_2), \\ (-\downarrow_C -)(u, \alpha, \beta, v) &= (u *_0 p_1, (\beta *_r p_2) *_c \gamma *_c (\alpha *_r p_1), v *_0 p_2), \end{aligned}$$

and we have to compute the composition of these two cells in  $\omega\text{-Cat}_{\text{oplax}}$ . We have

$$\begin{aligned} & \left( u' *_0 p'_1, (\beta' *_r p'_2) *_c \gamma' *_c (\alpha' *_r p'_1), v' *_0 p'_2 \right) \\ & *_0 \left( u *_0 p_1, (\beta *_r p_2) *_c \gamma *_c (\alpha *_r p_1), v *_0 p_2 \right) \\ &= \left( u' *_0 (u *_0 p_1), \right. \\ & \quad \left. [\beta' *_r (v *_0 p_2)] *_c [(\beta *_r p_2) *_c \gamma *_c (\alpha *_r p_1)] *_c [\alpha' *_r (u *_0 p_1)], \right. \\ & \quad \left. v' *_0 (v *_0 p_2) \right). \end{aligned}$$

The axiom we are checking is thus equivalent to the equalities

$$u' *_0 (u *_0 p_1) = (u' *_0 u) *_0 p_1, \quad v' *_0 (v *_0 p_2) = (v' *_0 v) *_0 p_2$$

and

$$\begin{aligned} & [\beta' *_r (v *_0 p_2)] *_c [(\beta *_r p_2) *_c \gamma *_c (\alpha *_r p_1)] *_c [\alpha' *_r (u *_0 p_1)] \\ &= [((\beta' *_r v) *_c \beta) *_r p_2] *_c \gamma *_c [(\alpha *_c (\alpha' *_r u)) *_r p_1]. \end{aligned}$$

The two first equalities are obviously true. As for the last one, we have

$$\begin{aligned} & [\beta' *_r (v *_0 p_2)] *_c [(\beta *_r p_2) *_c \gamma *_c (\alpha *_r p_1)] *_c [\alpha' *_r (u *_0 p_1)] \\ &= \left( [\beta' *_r (v *_0 p_2)] *_c [\beta *_r p_2] \right) *_c \gamma *_c \left( [\alpha *_r p_1] *_c [\alpha' *_r (u *_0 p_1)] \right) \\ &= \left( [((\beta' *_r v) *_r p_2)] *_c [\beta *_r p_2] \right) *_c \gamma *_c \left( [\alpha *_r p_1] *_c [(\alpha' *_r u) *_r p_1] \right) \\ &= [((\beta' *_r v) *_c \beta) *_r p_2] *_c \gamma *_c [(\alpha *_c (\alpha' *_r u)) *_r p_1], \end{aligned}$$

where the first equality follows from the associativity of  $*_c$ , the second from the fact that  $*_r$  is a right module action (see 4.2) and the last one from the fact that this action is compatible with  $*_c$  (see the last square of 4.5).  $\square$

**Corollary 5.4.** — *If  $B \rightarrow C$  is an  $\omega$ -functor, then we have a Gray  $\omega$ -functor*

$$-\downarrow_C B: \omega\text{-Cat}_{\text{oplax}}/C \rightarrow \omega\text{-Cat}_{\text{oplax}},$$

and if  $A \rightarrow C$  is an  $\omega$ -functor, then we have a Gray  $\omega$ -functor

$$A \downarrow_C -: \omega\text{-Cat}_{\text{oplax}}/C \xrightarrow{\text{to}} \omega\text{-Cat}_{\text{oplax}}.$$

**Remark 5.5.** — If  $A$  and  $B$  are two fixed  $\omega$ -categories, there is a canonical embedding

$$\underline{\text{Hom}}_{\text{oplax}}(A, C)^{\circ} \times \underline{\text{Hom}}_{\text{oplax}}(B, C)^{\text{to}} \hookrightarrow \omega\text{-Cat}_{\text{oplax}}/C \times \omega\text{-Cat}_{\text{oplax}}/C.$$

Indeed, by Proposition 4.12, the  $\omega$ -category  $\underline{\mathbf{Hom}}_{\text{oplax}}(A, C)^\circ$  canonically embeds in  $\omega\text{-Cat}_{\text{oplax}}/C$ , and, by duality, this implies that

$$\left(\underline{\mathbf{Hom}}_{(\omega\text{-Cat}_{\text{oplax}})^{\text{to}}}(A, C)^\circ\right)^{\text{to}} = \underline{\mathbf{Hom}}_{(\omega\text{-Cat}_{\text{oplax}})^{\text{to}}}(A, C)^{\text{t}} = \underline{\mathbf{Hom}}_{\omega\text{-Cat}_{\text{oplax}}}(A, C)^{\text{to}}$$

embeds in  $\omega\text{-Cat}_{\text{oplax}}/C$ .

The comma construction thus restricts to a Gray  $\omega$ -functor

$$-\downarrow_C - : \underline{\mathbf{Hom}}_{\text{oplax}}(A, C)^\circ \times \underline{\mathbf{Hom}}_{\text{oplax}}(B, C)^{\text{to}} \rightarrow \omega\text{-Cat}_{\text{oplax}}.$$

**Remark 5.6.** — By duality, one can deduce that the *lax* comma construction  $-\downarrow' -$  (see 3.7) defines a *skew* Gray  $\omega$ -functor. This follows from the formula  $A \downarrow'_C B \simeq (A^{\text{co}} \downarrow_{C^{\text{co}}} B^{\text{co}})^{\text{co}}$  (see again 3.7). Indeed, by 2.26, the operation  $X \mapsto X^{\text{co}}$  defines an isomorphism of Gray  $\omega$ -categories  $D_{\text{co}} : (\omega\text{-Cat}_{\text{lax}})^{\text{top}} \rightarrow \omega\text{-Cat}_{\text{oplax}}$  and an isomorphism of skew Gray  $\omega$ -categories  $D'_{\text{co}} : (\omega\text{-Cat}_{\text{oplax}})^{\text{top}} \rightarrow \omega\text{-Cat}_{\text{lax}}$ , and we can consider the chain of skew Gray  $\omega$ -functors

$$\begin{array}{c} ((\omega\text{-Cat}_{\text{lax}})^{\text{top}}/C)^{\text{top}} \times ((\omega\text{-Cat}_{\text{lax}})^{\text{top}}/C)^{\text{top}} \\ \downarrow \\ (\omega\text{-Cat}_{\text{oplax}}/C^{\text{co}})^{\text{top}} \times (\omega\text{-Cat}_{\text{oplax}}/C^{\text{co}})^{\text{top}} \xrightarrow{-\downarrow_{C^{\text{co}}} -} (\omega\text{-Cat}_{\text{oplax}})^{\text{top}} \xrightarrow{D'_{\text{co}}} \omega\text{-Cat}_{\text{lax}}, \end{array}$$

where the vertical arrow is induced by  $D_{\text{co}}$ . Composing this chain, we get a skew Gray  $\omega$ -functor

$$-\downarrow'_C - : \omega\text{-Cat}_{\text{lax}}/C^{\text{top}} \times \omega\text{-Cat}_{\text{lax}}/C^{\text{co}} \rightarrow \omega\text{-Cat}_{\text{lax}}.$$

**Remark 5.7.** — The two Gray  $\omega$ -functors of Corollary 5.4 can be deduced from each other using the formula  $A \downarrow_C B \simeq (B^\circ \downarrow_{C^\circ} A^\circ)^\circ$  of 3.7. For instance, if  $u : A \rightarrow C$  is an  $\omega$ -functor, the Gray  $\omega$ -functor  $A \downarrow_C -$  can be identified to the composition of the Gray  $\omega$ -functors

$$((\omega\text{-Cat}_{\text{oplax}})^{\text{to}}/C)^{\text{to}} \xrightarrow{D_\circ} (\omega\text{-Cat}_{\text{oplax}}/C^\circ)^{\text{to}} \xrightarrow{-\downarrow_{C^\circ} A^\circ} (\omega\text{-Cat}_{\text{oplax}})^{\text{to}} \xrightarrow{D_\circ} \omega\text{-Cat}_{\text{oplax}}.$$

We end the section by expressing that the comma construction of  $A \downarrow_C B$  is above  $A$  and  $B$  via a strict transformation.

**Proposition 5.8.** — *Let  $C$  be an  $\omega$ -category. The canonical projection*

$$p = (p_1, p_2) : A \downarrow_C B \rightarrow A \times B$$

*is natural in*

$$A \longrightarrow C \longleftarrow B,$$

*in the sense that it defines a strict transformation (see 2.14) from the Gray  $\omega$ -functor*

$$-\downarrow_C - : \omega\text{-Cat}_{\text{oplax}}/C \times \omega\text{-Cat}_{\text{oplax}}/C^{\text{to}} \rightarrow \omega\text{-Cat}_{\text{oplax}}$$

to the Gray  $\omega$ -functor obtained by composing

$$\omega\text{-Cat}_{\text{oplax}}/C \times \omega\text{-Cat}_{\text{oplax}}^{\text{to}}/C \xrightarrow{U \times U} \omega\text{-Cat}_{\text{oplax}} \times \omega\text{-Cat}_{\text{oplax}} \xrightarrow{\times} \omega\text{-Cat}_{\text{oplax}},$$

where  $U$  denotes the forgetful Gray  $\omega$ -functor (see 4.10) and  $\times$  is the product Gray  $\omega$ -functor (see 1.6).

*Proof.* — Let  $A, A', B$  and  $B'$  be four  $\omega$ -categories above  $C$ . Using the same abbreviation as in the proof of Theorem 5.3, we have to show the commutativity of the square

$$\begin{array}{ccc} \underline{\text{Hom}}_{/C}(A, A') \times \underline{\text{Hom}}_{/C}^{\text{to}}(B, B') & \xrightarrow{-\downarrow_C-} & \underline{\text{Hom}}_{\text{ol}}(A \downarrow_C B, A' \downarrow_C B') \\ \times \downarrow & & \downarrow \underline{\text{Hom}}_{\text{ol}}(A \downarrow_C B, p') \\ \underline{\text{Hom}}_{\text{ol}}(A \times B, A' \times B') & \xrightarrow{\underline{\text{Hom}}_{\text{ol}}(p, A' \downarrow_C B')} & \underline{\text{Hom}}_{\text{ol}}(A \downarrow_C B, A' \times B') \quad , \end{array}$$

where we denoted simply by  $\times$  the target Gray  $\omega$ -functor of the statement. So let  $(u, \alpha, \beta, v)$  be a cell in the source  $\omega$ -category of this square. Using the formula defining the Gray comma construction, we get that this cell is sent to  $(u *_0 p_1, v *_0 p_2)$  in  $\underline{\text{Hom}}_{\text{ol}}(A \downarrow_C B, A' \times B')$  by the upper path of the square. But the Gray  $\omega$ -functor  $\times$  send this same cell to  $(u *_0 q_1, v *_0 q_2)$  in  $\underline{\text{Hom}}_{\text{ol}}(A \times B, A' \times B')$ , where  $q_1: A \times B \rightarrow A$  and  $q_2: A \times B \rightarrow B$  are the two projections, and since

$$(u *_0 q_1, v *_0 q_2) *_0 p = (u *_0 q_1 *_0 p, v *_0 q_2 *_0 p) = (u *_0 p_1, v *_0 p_2),$$

the square indeed commutes.  $\square$

## 6. Strict functorialities of the comma construction

The purpose of this section is to study the functorialities of the comma construction when restricted to higher strict transformations.

**6.1.** — Fix  $C$  an  $\omega$ -category. The inclusion  $\omega\text{-Cat}_{\text{cart}} \hookrightarrow \omega\text{-Cat}_{\text{oplax}}$  induces inclusions

$$\omega\text{-Cat}_{\text{cart}}/C \hookrightarrow \omega\text{-Cat}_{\text{oplax}}/C \quad \text{and} \quad \omega\text{-Cat}_{\text{cart}}^{\text{to}}/C \hookrightarrow \omega\text{-Cat}_{\text{oplax}}^{\text{to}}/C.$$

In particular, we can restrict the Gray  $\omega$ -functor

$$-\downarrow_C-: \omega\text{-Cat}_{\text{oplax}}/C \times \omega\text{-Cat}_{\text{oplax}}^{\text{to}}/C \rightarrow \omega\text{-Cat}_{\text{oplax}}$$

to a Gray  $\omega$ -functor

$$-\downarrow_C-: \omega\text{-Cat}_{\text{cart}}/C \times \omega\text{-Cat}_{\text{cart}}^{\text{to}}/C \rightarrow \omega\text{-Cat}_{\text{oplax}}.$$

The goal of what follows is to prove that this Gray  $\omega$ -functor actually lands in  $\omega\text{-Cat}_{\text{cart}}$ .

The strategy is obvious. We gave in 5.2 a formula for this Gray  $\omega$ -functor and it suffices to check that the formula defines a cell of  $\omega\text{-Cat}_{\text{cart}}$ . But this formula involves

the oplax transformation  $\gamma$  of the universal 2-square which does not live in  $\omega\text{-Cat}_{\text{cart}}$ ! Nevertheless, we will see that the result is indeed in  $\omega\text{-Cat}_{\text{cart}}$ . To do so, we will introduce an intermediate slice  $\omega$ -category

$$\omega\text{-Cat}_{\text{cart}}/C \hookrightarrow \omega\text{-Cat}_{\text{cart}/\Gamma}C \hookrightarrow \omega\text{-Cat}_{\text{oplax}}/C$$

based on the inclusions

$$\Gamma\text{Hom}(A, B) \hookrightarrow \text{Hom}(A, \Gamma B) \hookrightarrow \Gamma\text{Hom}_{\text{oplax}}(A, B)$$

of 2.20.

**6.2.** — Let  $A$  and  $B$  be two  $\omega$ -categories. As mentioned above, we defined in 2.20 inclusions

$$\Gamma\text{Hom}(A, B) \hookrightarrow \text{Hom}(A, \Gamma B) \hookrightarrow \Gamma\text{Hom}_{\text{oplax}}(A, B)$$

factorising the canonical inclusion.

If  $B$  is fixed and  $A$  varies, we get inclusions

$$\Gamma\text{Hom}(-, B) \hookrightarrow \text{Hom}(-, \Gamma B) \hookrightarrow \Gamma\text{Hom}_{\text{oplax}}(-, B)$$

of skew Gray  $\omega$ -functors from  $(\omega\text{-Cat}_{\text{cart}})^{\dagger}$  to  $\omega\text{-Cat}_{\text{lax}}$ , and hence by Proposition 1.10, inclusions of right sub- $\omega\text{-Cat}_{\text{cart}}$ -modules. In particular, this means that if  $\alpha$  is a cell of  $\text{Hom}(A', \Gamma B)$  and  $u$  is a cell of  $\text{Hom}(A, A')$ , then  $\alpha *_r u$ , where  $*_r$  denotes the right action of 4.2, is a cell of  $\text{Hom}(A, \Gamma B)$ .

Moreover, for the same reasons as in 4.4, each of the three  $\omega$ -categories

$$\Gamma\text{Hom}(A, B) \hookrightarrow \text{Hom}(A, \Gamma B) \hookrightarrow \Gamma\text{Hom}_{\text{oplax}}(A, B)$$

is the object of morphisms of a category internal to  $\omega\text{-Cat}$  and, by naturality, the two inclusions are morphisms of internal categories. In particular, if  $\alpha$  and  $\beta$  are  $k$ -cells of  $\text{Hom}(A, \Gamma B)$  such that  $\mathfrak{t}(\beta) = \mathfrak{s}(\alpha)$ , then  $\beta *_c \alpha$ , where  $*_c$  denotes the internal composition of cylinders of 2.9, is a  $k$ -cell of  $\text{Hom}(A, \Gamma B)$ .

**6.3.** — Fix  $C$  an  $\omega$ -category. We define an  $\omega$ -category  $\omega\text{-Cat}_{\text{cart}/\Gamma}C$  in the following way:

The objects of  $\omega\text{-Cat}_{\text{cart}/\Gamma}C$  are the same as the ones of  $\omega\text{-Cat}_{\text{cart}}/C$  or of  $\omega\text{-Cat}_{\text{oplax}}/C$ , that is,  $\omega$ -categories  $A$  endowed with an  $\omega$ -functor  $f: A \rightarrow C$ .

If  $(A, f: A \rightarrow C)$  and  $(A', f': A' \rightarrow C)$  are two such objects, we set

$$\begin{aligned} & \text{Hom}_{\omega\text{-Cat}_{\text{cart}/\Gamma}C}((A, f), (A', f')) \\ &= \text{Hom}(A, A') \times_{\text{Hom}(A, C)} \text{Hom}(A, \Gamma C) \times_{\text{Hom}(A, C)} \{f\}. \end{aligned}$$

For the moment,  $\omega\text{-Cat}_{\text{cart}/\Gamma}C$  has only been defined as a graph enriched in  $\omega\text{-Cat}$ .

Recall that

$$\begin{aligned} & \text{Hom}_{\omega\text{-Cat}_{\text{cart}}/C}((A, f), (A', f')) \\ &= \text{Hom}(A, A') \times_{\text{Hom}(A, C)} \Gamma\text{Hom}(A, C) \times_{\text{Hom}(A, C)} \{f\} \end{aligned}$$

and

$$\begin{aligned} & \underline{\mathbf{Hom}}_{\omega\text{-Cat}_{\text{oplax}/C}}((A, f), (A', f')) \\ &= \underline{\mathbf{Hom}}_{\text{oplax}}(A, A') \times \underline{\mathbf{Hom}}_{\text{oplax}}(A, C) \Gamma \underline{\mathbf{Hom}}_{\text{oplax}}(A, C) \times \underline{\mathbf{Hom}}_{\text{oplax}}(A, C) \{f\}. \end{aligned}$$

Therefore, the monomorphisms

$$\Gamma \underline{\mathbf{Hom}}(A, C) \hookrightarrow \underline{\mathbf{Hom}}(A, \Gamma C) \hookrightarrow \Gamma \underline{\mathbf{Hom}}_{\text{oplax}}(A, C),$$

as they are compatible with the source and target operations of internal categories, induce monomorphisms between these fiber products and hence monomorphisms of graphs enriched in  $\omega\text{-Cat}$

$$\omega\text{-Cat}_{\text{cart}/C} \hookrightarrow \omega\text{-Cat}_{\text{cart}/\Gamma C} \hookrightarrow \omega\text{-Cat}_{\text{oplax}/C}.$$

We will consider these monomorphisms as inclusions. Note that  $\omega\text{-Cat}_{\text{cart}/\Gamma C}$  have not only the same objects as  $\omega\text{-Cat}_{\text{oplax}/C}$  but also the same 1-cells. (But their  $k$ -cells differ for  $k > 1$ .)

**Proposition 6.4.** — *If  $C$  is an  $\omega$ -category, then  $\omega\text{-Cat}_{\text{cart}/\Gamma C}$  is a sub-Gray  $\omega$ -category of  $\omega\text{-Cat}_{\text{oplax}/C}$ . It is actually a strict  $\omega$ -category.*

*Proof.* — Let  $(A, f: A \rightarrow C)$ ,  $(A', f': A' \rightarrow C)$  and  $(A'', f'': A'' \rightarrow C)$  be three objects of  $\omega\text{-Cat}/\Gamma C$  and let  $(u, \alpha)$  be a cell of  $\underline{\mathbf{Hom}}_{\omega\text{-Cat}/\Gamma C}((A, f), (A', f'))$  and  $(u', \alpha')$  a cell of  $\underline{\mathbf{Hom}}_{\omega\text{-Cat}/\Gamma C}((A', f'), (A'', f''))$ . By definition, their composition in  $\omega\text{-Cat}_{\text{oplax}/C}$  is given by

$$(u', \alpha') *_0 (u, \alpha) = (u' *_0 u, \alpha *_c (\alpha' *_r u)),$$

where  $*_r$  denotes the right action of 4.2 and  $*_c$  denotes the internal composition on  $\Gamma \underline{\mathbf{Hom}}_{\text{oplax}}(A, C)$  of 2.9. Since  $\omega\text{-Cat}_{\text{cart}}$  is a sub-Gray  $\omega$ -category of  $\omega\text{-Cat}_{\text{oplax}}$ , the cell  $u' *_0 u$  lives in  $\omega\text{-Cat}_{\text{cart}}$ . Moreover, by 6.2, the cell  $\alpha' *_r u$  is in  $\underline{\mathbf{Hom}}(A, \Gamma C)$  and hence so is  $\alpha *_c (\alpha' *_r u)$ , thereby proving the stability under composition of  $\omega\text{-Cat}_{\text{cart}/\Gamma C}$ . The compatibility with units is obvious.

The fact that  $\omega\text{-Cat}_{\text{cart}/\Gamma C}$  is a strict  $\omega$ -category follows from the formula giving the composition and the fact that  $\omega\text{-Cat}_{\text{cart}}$  is a strict  $\omega$ -category.  $\square$

**6.5.** — Let  $C$  be an  $\omega$ -category. One defines similarly an  $\omega$ -category  $\omega\text{-Cat}_{\text{cart}/\Gamma C}^{\text{to}}$  with Gray inclusions

$$\omega\text{-Cat}_{\text{cart}/C}^{\text{to}} \hookrightarrow \omega\text{-Cat}_{\text{cart}/\Gamma C}^{\text{to}} \hookrightarrow \omega\text{-Cat}_{\text{oplax}/C}^{\text{to}}.$$

The objects of  $\omega\text{-Cat}_{\text{cart}/\Gamma C}^{\text{to}}$  are the  $\omega$ -categories  $B$  endowed with an  $\omega$ -functor  $g: B \rightarrow C$ , and if  $(B, g: B \rightarrow C)$  and  $(B', g': B' \rightarrow C)$  are two such objects, we have

$$\begin{aligned} & \underline{\mathbf{Hom}}_{\omega\text{-Cat}/\Gamma C}^{\text{to}}((B, g), (B', g')) \\ &= \{g\} \times \underline{\mathbf{Hom}}_{(B, C)} \underline{\mathbf{Hom}}(B, \Gamma C) \times \underline{\mathbf{Hom}}_{(B, C)} \underline{\mathbf{Hom}}(B, B'). \end{aligned}$$

**Proposition 6.6.** — *Let  $C$  be an  $\omega$ -category. The Gray  $\omega$ -functor*

$$-\downarrow_C - : \omega\text{-Cat}_{\text{oplax}/C} \times \omega\text{-Cat}_{\text{oplax}/C}^{\text{to}} \rightarrow \omega\text{-Cat}_{\text{oplax}}$$

*induces an  $\omega$ -functor*

$$-\downarrow_C - : \omega\text{-Cat}_{\text{cart}/\Gamma C} \times \omega\text{-Cat}_{\text{cart}/\Gamma C}^{\text{to}} \rightarrow \omega\text{-Cat}_{\text{cart}}$$

*and in particular an  $\omega$ -functor*

$$-\downarrow_C - : \omega\text{-Cat}_{\text{cart}/C} \times \omega\text{-Cat}_{\text{cart}/C}^{\text{to}} \rightarrow \omega\text{-Cat}_{\text{cart}}.$$

*Proof.* — Consider  $A, A', B$  and  $B'$  four  $\omega$ -categories over  $C$ . We have to show that the composite  $\omega$ -functor

$$\begin{array}{ccc} \underline{\text{Hom}}_{\omega\text{-Cat}_{\text{cart}/\Gamma C}}((A, f), (A', f')) \times \underline{\text{Hom}}_{\omega\text{-Cat}_{\text{cart}/\Gamma C}^{\text{to}}}((B, g), (B', g')) & & \\ \downarrow & & \\ \underline{\text{Hom}}_{\omega\text{-Cat}_{\text{oplax}/C}}((A, f), (A', f')) \times \underline{\text{Hom}}_{\omega\text{-Cat}_{\text{oplax}/C}^{\text{to}}}((B, g), (B', g')) & & \\ \downarrow -\downarrow_C - & & \\ \underline{\text{Hom}}_{\text{oplax}}(A \downarrow_C B, A') & \downarrow & \underline{\text{Hom}}_{\text{oplax}}(A \downarrow_C B, B') \\ & \underline{\text{Hom}}_{\text{oplax}}(A \downarrow_C B, C) & \\ & \simeq & \\ & \underline{\text{Hom}}_{\text{oplax}}(A \downarrow_C B, A' \downarrow_C B') & \end{array}$$

factors through

$$\underline{\text{Hom}}(A \downarrow_C B, A' \downarrow_C B').$$

Using 5.2, and with its notation, this  $\omega$ -functor is given on  $k$ -cells by

$$(u, \alpha, \beta, v) \mapsto (u *_0 p_1, (\beta *_r p_2) *_c \gamma *_c (\alpha *_r p_1), v *_0 p_2),$$

where

$$(u, \alpha, \beta, v) \text{ is in } \underline{\text{Hom}}(A, A')_k \times \underline{\text{Hom}}(A, \Gamma C)_k \times \underline{\text{Hom}}(B, \Gamma C)_k \times \underline{\text{Hom}}(B, B')_k.$$

Note that  $\gamma$  can be seen as a 0-cell of  $\underline{\text{Hom}}(A \downarrow_C B, \Gamma C)$ . Using 6.2, we get that

$$(\beta *_r p_2) *_c \gamma *_c (\alpha *_r p_1)$$

is actually a  $k$ -cell in  $\underline{\text{Hom}}(A \downarrow_C B, \Gamma C)$ , and in particular,

$$(u *_0 p_1, (\beta *_r p_2) *_c \gamma *_c (\alpha *_r p_1), v *_0 p_2)$$

is a  $k$ -cell of

$$\frac{\underline{\text{Hom}}(A \downarrow_C B, A')}{\underline{\text{Hom}}(A \downarrow_C B, C)} \times \frac{\underline{\text{Hom}}(A \downarrow_C B, \Gamma C)}{\underline{\text{Hom}}(A \downarrow_C B, C)} \times \frac{\underline{\text{Hom}}(A \downarrow_C B, B')}{\underline{\text{Hom}}(A \downarrow_C B, C)},$$

which is canonically isomorphic to

$$\underline{\text{Hom}}(A \downarrow_C B, A' \times_C \Gamma C \times_C B') \simeq \underline{\text{Hom}}(A \downarrow_C B, A' \downarrow_C B').$$

As this canonical isomorphism is compatible with the canonical isomorphism between

$$\underline{\mathbf{Hom}}_{\text{oplax}}(A \downarrow_C B, A') \times \frac{\underline{\mathbf{Hom}}_{\text{oplax}}(A \downarrow_C B, \Gamma C)}{\underline{\mathbf{Hom}}_{\text{oplax}}(A \downarrow_C B, C)} \times \frac{\underline{\mathbf{Hom}}_{\text{oplax}}(A \downarrow_C B, B')}{\underline{\mathbf{Hom}}_{\text{oplax}}(A \downarrow_C B, C)}$$

and

$$\underline{\mathbf{Hom}}_{\text{oplax}}(A \downarrow_C B, A' \times_C \Gamma C \times_C B') \simeq \underline{\mathbf{Hom}}_{\text{oplax}}(A \downarrow_C B, A' \downarrow_C B'),$$

this proves the result.  $\square$

**Remark 6.7.** — As in Remark 5.5, if  $A$  and  $B$  are two fixed  $\omega$ -categories, there is a canonical embedding

$$\underline{\mathbf{Hom}}(A, C)^\circ \times \underline{\mathbf{Hom}}(B, C)^{\text{to}} \hookrightarrow \omega\text{-Cat}_{\text{cart}/C} \times \omega\text{-Cat}_{\text{cart}/C}^{\text{to}}$$

and the comma construction thus restricts to an  $\omega$ -functor

$$-\downarrow_C -: \underline{\mathbf{Hom}}(A, C)^\circ \times \underline{\mathbf{Hom}}(B, C)^{\text{to}} \rightarrow \omega\text{-Cat}_{\text{cart}}.$$

Similarly, if  $A$  is an  $\omega$ -category, let us denote by  $\underline{\mathbf{Hom}}_\Gamma(A, B)$  the total dual of the fiber at  $A$  of the forgetful  $\omega$ -functor

$$U: \omega\text{-Cat}_{\text{cart}/\Gamma C} \rightarrow \omega\text{-Cat}_{\text{cart}},$$

so that we have inclusions

$$\underline{\mathbf{Hom}}(A, C) \hookrightarrow \underline{\mathbf{Hom}}_\Gamma(A, C) \hookrightarrow \underline{\mathbf{Hom}}_{\text{oplax}}(A, C).$$

By definition (and duality), we have a canonical embedding

$$\underline{\mathbf{Hom}}_\Gamma(A, C)^\circ \times \underline{\mathbf{Hom}}_\Gamma(B, C)^{\text{to}} \hookrightarrow \omega\text{-Cat}_{\text{cart}/C} \times \omega\text{-Cat}_{\text{cart}/C}^{\text{to}}$$

and the comma construction also restricts to an  $\omega$ -functor

$$-\downarrow_C -: \underline{\mathbf{Hom}}_\Gamma(A, C)^\circ \times \underline{\mathbf{Hom}}_\Gamma(B, C)^{\text{to}} \rightarrow \omega\text{-Cat}_{\text{cart}}.$$

**Corollary 6.8.** — *If  $B \rightarrow C$  is an  $\omega$ -functor, then we have an  $\omega$ -functor*

$$-\downarrow_C B: \omega\text{-Cat}_{\text{cart}/\Gamma C} \rightarrow \omega\text{-Cat}_{\text{cart}}$$

*and in particular an  $\omega$ -functor*

$$-\downarrow_C B: \omega\text{-Cat}_{\text{cart}/C} \rightarrow \omega\text{-Cat}_{\text{cart}},$$

*and if  $A \rightarrow C$  is an  $\omega$ -functor, then we have an  $\omega$ -functor*

$$A \downarrow_C -: \omega\text{-Cat}_{\text{cart}/\Gamma C}^{\text{to}} \rightarrow \omega\text{-Cat}_{\text{cart}}$$

*and in particular an  $\omega$ -functor*

$$A \downarrow_C -: \omega\text{-Cat}_{\text{cart}/C}^{\text{to}} \rightarrow \omega\text{-Cat}_{\text{cart}}.$$

**Remark 6.9.** — By duality (see Remark 5.6), Proposition 6.6 implies that the lax comma construction induces an  $\omega$ -functor

$$-\downarrow'_C -: \omega\text{-Cat}_{\text{cart}}^{\text{top}} / C \times \omega\text{-Cat}_{\text{cart}}^{\text{co}} / C \rightarrow \omega\text{-Cat}_{\text{cart}} ,$$

and, more generally, an  $\omega$ -functor

$$-\downarrow'_C -: \omega\text{-Cat}_{\text{cart}/\Gamma'}^{\text{top}} C \times \omega\text{-Cat}_{\text{cart}/\Gamma'}^{\text{co}} C \rightarrow \omega\text{-Cat}_{\text{cart}} ,$$

where the  $\omega$ -categories

$$\omega\text{-Cat}_{\text{cart}/\Gamma'}^{\text{top}} C \quad \text{and} \quad \omega\text{-Cat}_{\text{cart}/\Gamma'}^{\text{co}} C$$

are defined from their undecorated-by- $\Gamma'$  analogue by replacing, in the definition of the  $\omega$ -category of morphisms,  $\Gamma' \underline{\text{Hom}}(-, C)$  by  $\underline{\text{Hom}}(-, \Gamma' C)$ . (Recall that  $\Gamma' X = \underline{\text{Hom}}_{\text{oplax}}(D_1, X)$ .)

## 7. Application: Grothendieck construction for $\omega$ -categories

Our main motivation for studying the functorialities of the comma construction was the Grothendieck construction for  $\omega$ -categories, to which we will devote a whole paper [2]. In this short final section, we define the Grothendieck construction for  $\omega$ -categories in terms of comma  $\omega$ -categories and we deduce functoriality results for the Grothendieck construction.

**7.1.** — Let  $I$  be an  $\omega$ -category and let  $F: I^\circ \rightarrow \omega\text{-Cat}_{\text{cart}}$  be an  $\omega$ -functor. We define the (contravariant) Grothendieck construction  $\int_I F$  of  $F$  to be the total dual of the comma construction of the diagram

$$D_0 \xrightarrow{D_0} \omega\text{-Cat}_{\text{cart}} \xleftarrow{F} I^\circ ,$$

where the left arrow corresponds to the object  $D_0$  of  $\omega\text{-Cat}_{\text{cart}}$ . In other words, we have

$$\int_I F = (D_0 \downarrow_{\omega\text{-Cat}_{\text{cart}}} F)^\circ .$$

The second projection of the comma construction induces an  $\omega$ -functor  $p: \int_I F \rightarrow I$ .

**Remark 7.2.** — Although the  $\omega$ -category  $\omega\text{-Cat}_{\text{cart}}$  is not small, the comma construction  $D_0 \downarrow F$  makes sense and is a small  $\omega$ -category.

**Remark 7.3.** — By Example 3.2, the Grothendieck construction of an  $\omega$ -functor  $F: I^\circ \rightarrow \omega\text{-Cat}_{\text{cart}}$  is the total dual of a relative slice:

$$\int_I F = (D_0 \downarrow F)^\circ = (D_0 \setminus I^\circ)^\circ .$$

In other words, we have a pullback square

$$\begin{array}{ccc} (\int_I F)^\circ & \longrightarrow & D_0 \backslash \omega\text{-Cat}_{\text{cart}} \\ \downarrow & \lrcorner & \downarrow U \\ I^\circ & \xrightarrow{F} & \omega\text{-Cat}_{\text{cart}} \end{array} ,$$

where  $U$  denotes the forgetful  $\omega$ -functor.

**7.4.** — Let  $F: I^\circ \rightarrow \omega\text{-Cat}_{\text{cart}}$  be an  $\omega$ -functor. To convince ourselves that our definition of the Grothendieck construction is reasonable, let us concretely describe the cells of  $\int_I F$  in low dimensions.

By definition, an object of  $\int_I F$  corresponds to an object  $i$  of  $I$  and an  $\omega$ -functor  $x: D_0 \rightarrow F(i)$ . These objects can thus be identified with pairs  $(i, x)$ , where  $i$  is an object of  $I$  and  $x$  an object of  $F(i)$ .

A 1-cell of  $\int_I F$  corresponds to a 1-cell  $f: i \rightarrow i'$  of  $I$  and a 2-triangle

in  $\omega\text{-Cat}_{\text{oplax}}$ . But the data of such an oplax transformation  $\alpha$  is equivalent to the data of a 1-cell  $\alpha: x \rightarrow F(f)(x')$  of  $F(i)$ . The 1-cells from  $(i, x)$  to  $(i', x')$  can thus be identified with pairs  $(f: i \rightarrow i', \alpha: x \rightarrow F(f)(x'))$ .

A 2-cell of  $\int_I F$  corresponds to 2-cell  $\gamma: f \Rightarrow f': i \rightarrow i'$  of  $I$  and a cone

in  $\omega\text{-Cat}_{\text{oplax}}$ . But the data of such an oplax 2-transformation  $\Lambda$  is equivalent to the data of a 2-cell  $\Lambda: \alpha \Rightarrow F(\gamma)_{x'} * \alpha'$  of  $F(i)$ . The 2-cells from  $(f, \alpha)$  to  $(f', \alpha')$  can thus be identified with these pairs  $(\gamma, \Lambda)$ .

**Remark 7.5.** — The Grothendieck construction for  $\omega$ -categories was first defined by Warren [9] using explicit formulas. In [2], we will show that our definition is equivalent to Warren’s one (up to some duality, as Warren defines the *covariant* Grothendieck construction).

**7.6.** — We will denote by  $\omega\text{-CAT}_{\text{oplax}}$  the (very large) Gray  $\omega$ -category of possibly large  $\omega$ -categories,  $\omega$ -functors, oplax transformations and higher oplax transformations between them. We have a fully faithful inclusion  $\omega\text{-Cat}_{\text{oplax}} \hookrightarrow \omega\text{-CAT}_{\text{oplax}}$ . The  $\omega$ -category  $\omega\text{-Cat}_{\text{cart}}$  is an object of  $\omega\text{-CAT}_{\text{oplax}}$ . When we consider  $\omega\text{-Cat}_{\text{cart}}$  as an object of  $\omega\text{-CAT}_{\text{oplax}}$ , we will denote it by  $\{\omega\text{-Cat}_{\text{cart}}\}$ . In particular, we will write

$$\omega\text{-Cat}_{\text{oplax}} / \{\omega\text{-Cat}_{\text{cart}}\}^{\text{to}}$$

for the Gray  $\omega$ -category defined by the pullback

$$\begin{array}{ccc} \omega\text{-Cat}_{\text{oplax}} / \{\omega\text{-Cat}_{\text{cart}}\}^{\text{to}} & \longrightarrow & \omega\text{-CAT}_{\text{oplax}} / \{\omega\text{-Cat}_{\text{cart}}\}^{\text{to}} \\ \downarrow & \lrcorner & \downarrow U \\ \omega\text{-Cat}_{\text{oplax}} & \hookrightarrow & \omega\text{-CAT}_{\text{oplax}} \end{array} ,$$

where  $\omega\text{-CAT}_{\text{oplax}} / \{\omega\text{-Cat}_{\text{cart}}\}^{\text{to}}$  is one of the (very large) slice Gray  $\omega$ -categories of 4.13 and  $U$  is the forgetful Gray  $\omega$ -functor.

**Theorem 7.7.** — *The Grothendieck construction defines a Gray  $\omega$ -functor*

$$\begin{array}{ccc} \int: (\omega\text{-Cat}_{\text{oplax}} / \{\omega\text{-Cat}_{\text{cart}}\}^{\text{to}})^{\text{to}} & \rightarrow & \omega\text{-Cat}_{\text{oplax}} \\ F: I^{\circ} \rightarrow \omega\text{-Cat}_{\text{cart}} & \mapsto & \int_I F \end{array} .$$

*Proof.* — The Grothendieck construction factors as

$$(\omega\text{-Cat}_{\text{oplax}} / \{\omega\text{-Cat}_{\text{cart}}\}^{\text{to}})^{\text{to}} \xrightarrow{D_0 \downarrow -} (\omega\text{-Cat}_{\text{oplax}})^{\text{to}} \xrightarrow{D_o} \omega\text{-Cat}_{\text{oplax}} ,$$

where  $D_o$  is the total dual. But the left arrow is a Gray  $\omega$ -functor by Theorem 5.3 (and more precisely Corollary 5.4) and the right arrow is a Gray  $\omega$ -functor by 2.26.  $\square$

**Proposition 7.8.** — *The  $\omega$ -functor  $p: \int_I F \rightarrow I$  is natural in  $F: I^{\circ} \rightarrow \omega\text{-Cat}_{\text{cart}}$  in the sense that it defines a strict transformation from the Gray  $\omega$ -functor*

$$\int: (\omega\text{-Cat}_{\text{oplax}} / \{\omega\text{-Cat}_{\text{cart}}\}^{\text{to}})^{\text{to}} \rightarrow \omega\text{-Cat}_{\text{oplax}}$$

*to the Gray  $\omega$ -functor obtained by composing*

$$(\omega\text{-Cat}_{\text{oplax}} / \{\omega\text{-Cat}_{\text{cart}}\}^{\text{to}})^{\text{to}} \xrightarrow{U} (\omega\text{-Cat}_{\text{oplax}})^{\text{to}} \xrightarrow{D_o} \omega\text{-Cat}_{\text{oplax}} ,$$

*where  $D_o$  is the total dual.*

*Proof.* — This is a particular case of the analogous result for the comma construction, that is, Proposition 5.8.  $\square$

**Proposition 7.9.** — *If  $I$  is a fixed  $\omega$ -category, the Grothendieck construction restricts to a Gray  $\omega$ -functor*

$$\int_I: \underline{\text{Hom}}_{\text{oplax}}(I^{\circ}, \omega\text{-Cat}_{\text{cart}}) \rightarrow \omega\text{-Cat}_{\text{oplax}} .$$

*Proof.* — By Remark 5.5, there is a canonical embedding

$$\underline{\mathbf{Hom}}_{\text{oplax}}(I^\circ, \omega\text{-Cat}_{\text{cart}})^{\text{to}} \hookrightarrow \omega\text{-Cat}_{\text{oplax}}^{\text{to}} / \{\omega\text{-Cat}_{\text{cart}}\},$$

hence the result by the previous proposition.  $\square$

**7.10.** — We are now going to state the strict functorialities of the Grothendieck construction. We can define, as in 7.6, a large strict  $\omega$ -category

$$\begin{array}{ccc} \omega\text{-Cat}_{\text{cart}}^{\text{to}} / \{\omega\text{-Cat}_{\text{cart}}\} & \longrightarrow & \omega\text{-CAT}_{\text{cart}}^{\text{to}} / \{\omega\text{-Cat}_{\text{cart}}\} \\ \downarrow & \lrcorner & \downarrow U \\ \omega\text{-Cat}_{\text{cart}} & \longleftarrow & \omega\text{-CAT}_{\text{cart}} \end{array} ,$$

where  $\omega\text{-CAT}_{\text{cart}}$  is the (very large) strict of  $\omega$ -category of possibly large  $\omega$ -categories,  $\omega$ -functors, strict transformations and higher strict transformations between them.

**Proposition 7.11.** — *The Grothendieck construction restricts to a strict  $\omega$ -functor*

$$\int: (\omega\text{-Cat}_{\text{cart}}^{\text{to}} / \{\omega\text{-Cat}_{\text{cart}}\})^{\text{to}} \rightarrow \omega\text{-Cat}_{\text{cart}} ,$$

and, if  $I$  is a fixed  $\omega$ -category, to a strict  $\omega$ -functor

$$\int_I: \underline{\mathbf{Hom}}(I^\circ, \omega\text{-Cat}_{\text{cart}}) \rightarrow \omega\text{-Cat}_{\text{cart}} .$$

*Proof.* — This follows from the analogous result for the comma construction, that is, Proposition 6.6.  $\square$

**Remark 7.12.** — By Remark 6.7 and using the same notation, the second  $\omega$ -functor of the above proposition actually extends to an  $\omega$ -functor

$$\int_I: \underline{\mathbf{Hom}}_\Gamma(I^\circ, \omega\text{-Cat}_{\text{cart}}) \rightarrow \omega\text{-Cat}_{\text{cart}} .$$

We end the paper by an opening on a definition of the Grothendieck construction for (skew) Gray  $\omega$ -functors, based on Remark 7.3.

**7.13.** — Let  $\mathbb{C}$  be a Gray  $\omega$ -category, so that  $\mathbb{C}^\circ$  is a skew Gray  $\omega$ -category, and fix  $F: \mathbb{C}^\circ \rightarrow \omega\text{-Cat}_{\text{lax}}$  a skew Gray  $\omega$ -functor. We define the *Grothendieck construction*  $\int_{\mathbb{C}} F$  of  $F$  as the Gray  $\omega$ -category obtained by taking the total dual of the pullback of skew Gray  $\omega$ -categories

$$\begin{array}{ccc} (\int_{\mathbb{C}} F)^\circ & \longrightarrow & D_0 \backslash \omega\text{-Cat}_{\text{lax}} \\ \downarrow & \lrcorner & \downarrow U \\ \mathbb{C}^\circ & \xrightarrow{F} & \omega\text{-Cat}_{\text{lax}} \end{array} ,$$

where  $D_0 \backslash \omega\text{-Cat}_{\text{lax}}$  is one of the slice skew Gray  $\omega$ -categories defined in 4.13 and  $U$  is the forgetful skew Gray  $\omega$ -functor.

By Remark 7.3, in the case where  $\mathbb{C}$  comes from a strict  $\omega$ -category and the  $\omega$ -functor  $F$  factors through  $\omega\text{-Cat}_{\text{cart}} \hookrightarrow \omega\text{-Cat}_{\text{fax}}$ , we recover the Grothendieck construction defined in 7.1.

In future work, we plan to investigate this Grothendieck construction for (skew) Gray  $\omega$ -functors.
