

FACE: Few-shot Adapter with Cross-view Fusion for Cross-subject EEG Emotion Recognition

Haiqi Liu *Student Member, IEEE*, C. L. Philip Chen *Life Fellow, IEEE*, Tong Zhang *Senior Member, IEEE*

Abstract—Cross-subject EEG emotion recognition is challenged by significant inter-subject variability and intricately entangled intra-subject variability. Existing works have primarily addressed these challenges through domain adaptation or generalization strategies. However, they typically require extensive target subject data or demonstrate limited generalization performance to unseen subjects. Recent few-shot learning paradigms attempt to address these limitations but often encounter catastrophic overfitting during subject-specific adaptation with limited samples. This article introduces the few-shot adapter with a cross-view fusion method called FACE for cross-subject EEG emotion recognition, which leverages dynamic multi-view fusion and effective subject-specific adaptation. Specifically, FACE incorporates a cross-view fusion module that dynamically integrates global brain connectivity with localized patterns via subject-specific fusion weights to provide complementary emotional information. Moreover, the few-shot adapter module is proposed to enable rapid adaptation for unseen subjects while reducing overfitting by enhancing adapter structures with meta-learning. Experimental results on three public EEG emotion recognition benchmarks demonstrate FACE’s superior generalization performance over state-of-the-art methods. FACE provides a practical solution for cross-subject scenarios with limited labeled data.

Index Terms—EEG emotion recognition, few shot learning, adapter, cross-view fusion.

I. INTRODUCTION

UNDERSTANDING Human emotions is fundamental and crucial to advancing fields such as human-computer interaction [1] and mental health [2]. Electroencephalography (EEG) has recently emerged as a remarkable tool for capturing subject’s neural responses to emotional states [3]. EEG-based emotion recognition remains challenging due to the substantial inter-subject variance in brain activity patterns [4], [5]. Additionally, intra-subject variance arises from the non-stationary nature of EEG signals, which exhibit variations in frequency and amplitude over time within the same subject. In most cases, these variances entangle with each other, diminishing

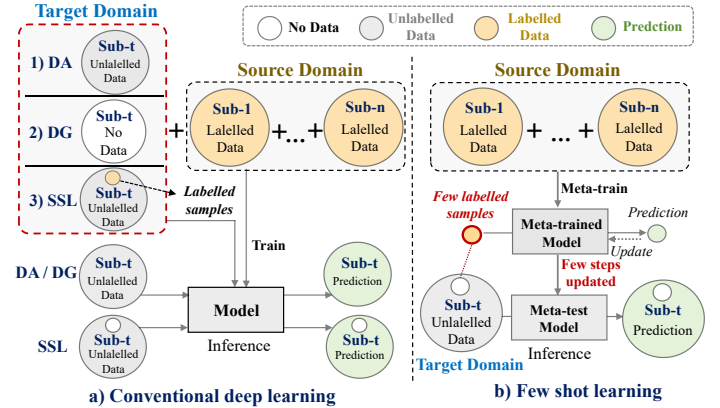

Fig. 1. Comparison of training data and processes between Few-Shot Learning (FSL) and traditional deep learning (DL) in cross-subject EEG emotion recognition. Traditional DL primarily relies on additional unlabeled target data for training, whereas FSL learns a subject-agnostic model in the source domain and fine-tunes it using only a few target-domain samples with few steps. DA denotes Domain Adaptation, DG denotes Domain Generalization, and SSL denotes Semi-Supervised Learning.

the ability of models trained on one group to generalize effectively to unseen subjects.

Existing studies are mainly dedicated to addressing the inter-subject variance through domain-adaptation and domain-generalization strategies. Domain-adaptation methods learn subject-specific representations by aligning the marginal distributions of source and target subjects [6]. Although these methods [5], [7], [8] have achieved notable results, they require large amounts of unlabeled target subject data during training. This requirement restricts their applicability in scenarios with scarce or non-specific target subject data [9]. In contrast, domain-generalization methods attempt to learn subject-invariant representations from source data [10]. However, they often struggle to generalize to unseen target domains due to their dependence on source data diversity [11]. Moreover, the absence of target domain data in training makes it challenging for these methods to estimate subtle domain shifts and capture target subject-specific patterns. Recently, few-shot learning [12] (FSL) approaches have emerged as a promising alternative to address this issue. These methods [13]–[15] leverage the FSL method to learn a whole subject-agnostic initialization that can quickly adapt to new subjects using only a few labeled samples (See Fig. 1). Nonetheless, the scarcity of labeled EEG data from target subjects often leads to catastrophic overfitting when performing whole model parameter updates with limited training steps. These limitations result in suboptimal performance for novel subjects. Based on these

observations, this article encourages a partial parameter update strategy for target subject adaptation, prioritizing rapid adaptation over full model fine-tuning. We introduce the Few-shot Adapter module which incorporates the adapter structure with the meta-learning paradigm. This design facilitates capturing subject-specific emotional discriminative cues while reducing overfitting under few-shot conditions.

Furthermore, addressing intra-individual variance in EEG signals remains challenging [16]. Earlier studies attempted to mitigate this issue by introducing statistical features such as power spectral density (PSD) and phase-locking value (PLV) to capture complementary information of the EEG signal [17]. However, these methods suffer from heterogeneous feature spaces that lead to redundant information and noise accumulation [18]. Recent work has shifted toward learning discriminative patterns automatically, leveraging multi-scale learning [19], contrastive learning [20], or spatial-temporal attention [21] within graph convolutional networks (GCNs). Although these approaches can reveal complex brain functional connectivity associated with emotion, they typically rely on a single view information or uniform fusion weights across all unseen subjects, limiting their capacity to fully exploit subject-specific discriminative details. It is reasonable to assume that fusion weights for different views should also be subject-specific because inter-subject variance is inherently coupled with intra-subject variance in EEG signals. To address this gap, this article proposes a cross-view fusion module that dynamically learns a unified representation across different views with subject-specific fusion weights.

To address the above challenges, this article proposes a few-shot adapter with a cross-view fusion framework named FACE for cross-subject EEG emotion recognition. Departing from existing FSL-based methods in this domain, FACE innovatively incorporates complementary spatial view information and encourages subject-specific adaptation from both the feature fusion and adjustment aspects only, thereby achieving superior cross-subject generalization. Specifically, FACE comprises two key components: a cross-view fusion (CVF) module and a few-shot adapter (FSA) module. Recent studies [22], [23] have demonstrated that emotional processing depends on both the activity of specific brain regions and the coordination of large-scale brain networks. Building on this insight, the CVF module extends the conventional GCN view by introducing a cross-view architecture. The GCN view extracts global connectivity patterns, while a complementary local view identifies region-specific emotional information. The CVF module projects two view representations into a shared space and performs subject-specific complementary fusion with meta-learning. Moreover, inspired by the adapter structure in the computer vision field, this article introduces a FSA module to enable rapid calibration for unseen subjects in the EEG emotion recognition task. Due to the significant inter-subject variability in EEG signals, this article incorporates batch normalization layers into each residual adapter layer to statistically regularize inter-subject variability. Moreover, the adapter employs a meta-learning paradigm to achieve more effective calibration. To the best of our knowledge, this is the first work to apply an adapter mechanism to address cross-

domain EEG emotion recognition. Comprehensive evaluations on three widely used benchmarks (SEED, SEED-IV, and SEED-V) demonstrate that FACE outperforms state-of-the-art cross-subject EEG emotion recognition methods.

In summary, this work presents the following contributions:

- 1) This article proposes FACE, a novel method to enhance cross-subject EEG emotion recognition through subject-specific adaptation via joint feature fusion and adjustment. Extensive experiments on three widely used benchmarks demonstrate that FACE achieves comparable performance with state-of-the-art approaches.
- 2) The CVF module effectively combines global brain connectivity and local patterns, utilizing meta-learned cross-view fusion. It dynamically provides comprehensive subject-specific unified representation.
- 3) The FSA module incorporates the adapter structure and meta-learning paradigm to enable rapid subject-specific emotional feature adjustment for unseen subjects.

The remainder of the article is organized as follows. Section II reviews the relevant literature. Section III details the proposed FACE model. Section IV presents the experimental results and comparative analysis. Section V critically examines the impact of each module and the parameter settings. Finally, Section VI summarizes our contributions and discusses future research directions.

II. RELATED WORK

A. Cross-Subject EEG Emotion Recognition

Cross-subject EEG emotion recognition has garnered significant attention due to its pivotal role in brain-computer interfaces [24]. The task is particularly challenging due to the inherent non-stationarity of EEG signals and the complexity of human emotional expression. Early approaches to this task focused on handcrafted statistical features combined with simple classifiers, which yielded limited performance [25]. Recent works [19], [20], [26] primarily address this issue in a supervised learning manner. Song *et al.* proposed the instance-adaptive graph network, which explores dynamic connectivity across brain regions [26]. GMSS [20] leveraged multi-task self-supervision for generalized representations. Jin *et al.* introduced the pyramidal GCN, which fully exploits multi-scale information to improve performance [19]. More recently, semi-supervised learning paradigms have been applied to EEG emotion recognition to refine individual-specific mappings better. Li *et al.* combined meta-learning and semi-supervised learning to facilitate subject-adaptation representations [27]. Guarneros *et al.* proposed semi-supervised multi-source joint distribution adaptation to align distributions across different subjects [28]. Despite these advances, supervised learning methods fail to explicitly model inter-subject variability, often resulting in poor performance for specific subjects. Additionally, semi-supervised methods require extensive unlabeled target data and suffer from multi-objective optimization instability. To address these issues, this article investigates the problem of few-shot cross-subject emotion recognition, relaxing the requirement for unlabeled data and learning subject-specific emotional representations with few labeled data from the target subject.

B. Inter-Subject Variance in EEG Emotion Recognition

Inter-subject variability in EEG emotion recognition mainly arises from individual differences in brain structure and cognitive processes. These variations pose significant challenges for developing generalized EEG emotion recognition models. Recently, Domain Adaptation (DA) and Domain Generalization (DG) techniques have emerged as promising solutions to mitigate the impact of inter-subject variance [29]. DA methods [5], [7], [8], [30] aim to bridge the distributional gaps between source and target subjects to improve the performance of the target subject. They leverage various divergence metrics (e.g. MMD [31]) to qualify and minimize distributional shifts. Chen *et al.* introduced a multi-source marginal distribution strategy to preserve the marginal distributions of EEG data during adaptation [7]. Li *et al.* proposed a dynamic domain adaptation approach, which dynamically adapts domains based on class-aware information [8]. Wu *et al.* developed the graph orthogonal purification network, which aligns the distribution of emotional features across dual spaces [5]. However, DA methods are limited in applicability due to their reliance on target subject information during training. Unlike DA, DG methods [4], [32]–[34] attempt to learn generalized models that perform well across multiple domains without relying on explicit adaptation to specific target domains. Chen *et al.* proposed a graph domain disentanglement network to learn subject-invariant representations [4]. Ugan [33] was introduced to model and constrain potential uncertain statistical shifts across individuals comprehensively. Liu *et al.* developed a sparse mixture of graph experts model, which learns transferable features by decomposing brain regions into simpler functional units [34]. Despite their effectiveness, these methods remain in suboptimal performance due to the absence of target domain information. This fundamental limitation drives our exploration of few-shot learning paradigms for EEG-based emotion recognition, particularly focusing on scenarios where only minimal labeled target subject data is available.

C. Few-shot Learning

Few-shot learning (FSL) is an advanced paradigm that facilitates rapid model adaptation to novel classes with only a few labeled examples [7], [35], [36]. This paradigm has recently gained attraction in brain-computer interface research. Ning *et al.* pioneered its application to cross-subject EEG-based emotion recognition by employing a prototypical network [37] for efficient cross-subject generalization [38]. Zhang *et al.* developed EmoDSN [39], a deep Siamese network architecture that achieves rapid convergence with minimal training data while maintaining robust performance in fine-grained emotion recognition tasks. These metric-learning-based methods, which focus on learning a metric space that generalizes to new subjects without requiring fine-tuning, exhibit similarities with DG methods [11]. Current research predominantly focuses on meta-learning strategies for cross-subject EEG emotion recognition. MetaEmotionNet [40] and MAML-EEG [14] adapted the model-agnostic meta-learning [41] framework to EEG emotion recognition, demonstrating promising performance on novel subjects. FreAML [13] introduced a Bayesian meta-

learning framework that derives task-specific model parameters from the frequency domain. SIML [15] further hybridized conventional supervised learning with meta-learning to optimize EEG classifier training. These methods generally aim to learn a subject-agnostic initialization that can quickly adapt to new subjects with few labeled samples. Despite these advances, existing methods face inherent limitations in computational efficiency and adaptation flexibility when handling heterogeneous neurophysiological patterns. Differently, this article advocates a partial parameter update strategy for target subject adaptation, emphasizing rapid adaptation while reducing overfitting over exhaustive model fine-tuning.

III. THE ADOPTED METHODOLOGY

This section introduces a few-shot adapter with a cross-view fusion approach for cross-subject EEG emotion recognition. The overall architecture of the proposed FACE framework is illustrated in Fig. 2. FACE consists of two core components: the few-shot adapter module and the cross-view fusion module. The following sections provide a detailed explanation of each component.

A. Problem Definition

In the cross-subject EEG emotion recognition task, each subject can be considered a distinct domain due to substantial inter-subject variance. Accordingly, the data is divided into a source domain for training and a target domain for testing. Let the source domain be defined as $\mathcal{D}_s = \{(\mathbf{x}_i, y_i, S_i)\}_{i=1}^N$, where $S_i \in S_{source}$ denotes the i -th source subject, $\mathbf{x}_i \in \mathcal{X}$ represents EEG signals, and $y_i \in \mathcal{Y}$ is the corresponding emotion label. The objective of cross-subject emotion recognition is to learn a model $f_\theta : \mathcal{X} \rightarrow \mathcal{Y}$ trained on \mathcal{D}_s that generalizes to unseen target subjects $S_t \in S_{target}$, where $S_{source} \cap S_{target} = \emptyset$. The core challenge arises from domain shifts between source and target subjects, characterized by $P(\mathbf{X} | S_s) \neq P(\mathbf{X} | S_t)$, where $S_s \in S_{source}$. Existing methods often leverage auxiliary data from the target domain, such as few labeled $\mathcal{D}_t^l = \{(\mathbf{x}_i, y_i, S_t), i = 1, \dots, j\}$ and $\mathcal{D}_t^u = \{\mathbf{x}, S_t\}$, to mitigate distribution shifts. The few shot cross-subject emotion recognition extends this task by imposing a strict few-shot constraint: For target subject S_t , the model must perform few-steps adaptation utilizing only a small support set $\mathcal{D}_t^{\text{sup}} = \{(\mathbf{x}_i, y_i)\}_{i=1}^{k \times c}$, where k ($k \leq 10$) represents the number of labeled samples per emotion class c , and generalize to the query set $\mathcal{D}_t^{\text{que}} = \{(\mathbf{x}_i, y_i)\}_{i=1}^M$. Here, M represents the total number of remaining unlabeled samples from the target subject after excluding $\mathcal{D}_t^{\text{sup}}$. This paradigm is referred to as a c -way k -shot task. Formally, the model f_θ initially trained on the source domain \mathcal{D}_s must generalize to target subject S_t via few steps optimization using limited labeled samples $\mathcal{D}_t^{\text{sup}}$, such that:

$$\min_{\theta'} \mathbb{E}_{(\mathbf{x}, y) \sim \mathcal{D}_{\text{que}}^{S_t}} [\mathcal{L}(f_{\theta'}(\mathbf{x}), y)], \quad (1)$$

where $f_{\theta'}$ is the updated model and $\mathcal{L}(\cdot)$ is the loss function, i.e., cross-entropy loss.

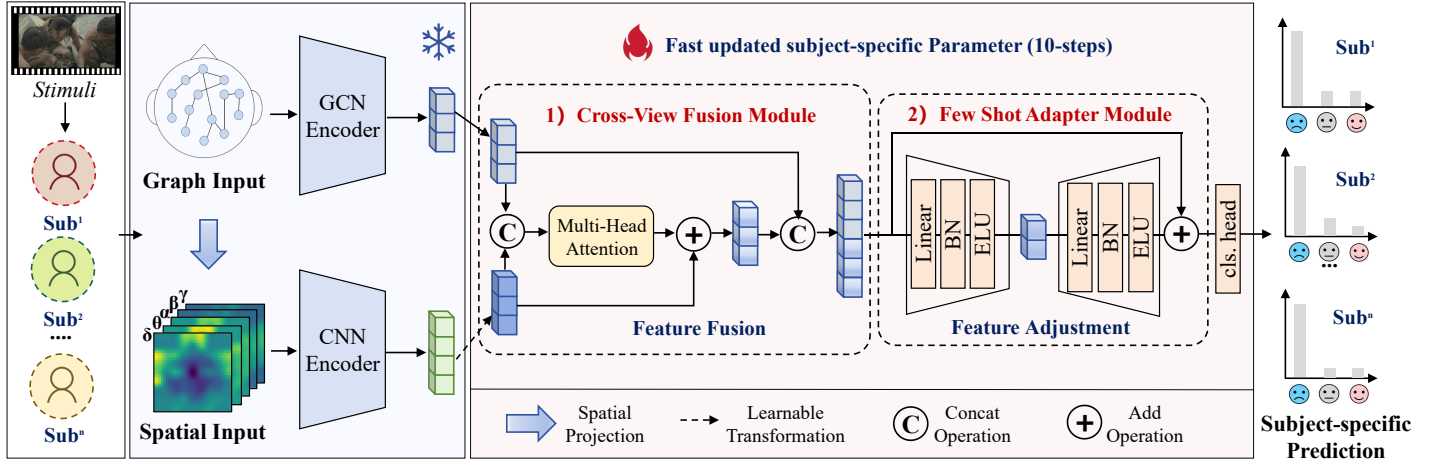

Fig. 2. Overview of the proposed FACE architecture in testing stage. For each unseen subject, a few labeled EEG signals are collected for rapid partial updates. Their EEG signals undergo spatial projection to construct spatial representations, which are then fed into FACE. The framework contains two core components: 1) The Cross-View Module fuses multi-view features to obtain unified representations, and 2) The Few-Shot Adapter Module adjusts the features to ensure subject-specific emotional clues is captured.

B. GCN Backbone

Current methodologies for EEG-based emotion recognition commonly employ GCNs to capture discriminative brain topology from EEG signals. This article employs the dynamic GCN (DGCN) [42] as the main encoder. EEG signals are pre-processed into differential entropy (DE) features across multiple frequency bands, forming representative feature $\mathbf{X} \in \mathbb{R}^{N \times C \times B}$ where N , C and B denote the number of samples, channels, and frequency bands, respectively. Each EEG sample $x \in \mathbf{X}$ can be represented as a graph $\mathcal{G} = (\mathcal{V}, \mathcal{E})$, where the node set $\mathcal{V} = \{v_1, \dots, v_C\}$ corresponds to EEG channels, and the edges \mathcal{E} are weighted by a dynamic adjacency matrix $\mathbf{A}_d \in \mathbb{R}^{C \times C}$ that quantifies pairwise channel dependencies. The dynamic adjacency matrix can be formulated as:

$$\mathbf{A}_d = \sigma_1(\mathbf{W}_2 \cdot \sigma_2(\mathbf{W}_1 \mathbf{A}_0)), \quad (2)$$

where σ_1 and σ_2 denote different activation functions. \mathbf{A}_0 represents a randomly initialized matrix, and $\mathbf{W}_1 \in \mathbb{R}^{C \times (\frac{C}{r})}$ and $\mathbf{W}_2 \in \mathbb{R}^{(\frac{C}{r} \times C)}$ are learnable projection matrices with a reduction ratio r .

The dynamic GCN processes \mathbf{X} through two-layers GCN to derive high-level representations which can be formally expressed as:

$$\mathbf{H} = \text{BN}(\Theta_2 * \sigma(\text{BN}(\Theta_1 * \mathbf{X}))), \quad (3)$$

where $\Theta_1, \Theta_2 \in \mathbb{R}^{1 \times K}$ are convolution kernels with stride 1, $*$ denotes convolution operation, and BN represents the batch normalization layer. The node aggregation is performed with residual operation to obtain the hierarchical feature representations, which can be expressed as:

$$\mathbf{Z}_g = \text{BN}(\mathbf{LH} + \mathbf{X}), \quad (4)$$

where $\mathbf{L} = \mathbf{D}^{-1} \mathbf{A}_d$ denotes the graph Laplacian. The hierarchical feature \mathbf{Z}_g is finally fed into a fully connected layer for final emotion classification. The final emotion prediction \hat{y} is obtained via:

$$\hat{y} = \text{Softmax}(\mathbf{Z}_g \mathbf{W}_c + b). \quad (5)$$

The model is optimized by minimizing the cross-entropy loss as follow:

$$\mathcal{L}_{\text{cls}} = -\frac{1}{N} \sum_{i=1}^N \sum_{j=1}^c y_{i,j} \log(\hat{y}_{i,j}), \quad (6)$$

where $y_{i,j}$ is the ground-truth one-hot label of the i -th sample, and $\hat{y}_{i,j}$ represents the prediction for class j .

C. Cross-view Fusion Module

While the DGCN can effectively capture global brain topology in EEG signals, local subtle patterns are equally critical for emotion recognition. To obtain stronger feature representation and mitigate the effects of intra-subject variability, this article proposes the cross-view fusion module which effectively integrates both global and spatial-local patterns.

1) *Spatial Feature Extraction*: EEG signals are recorded from multiple scalp-mounted electrodes. Each electrode monitors electrical activity in specific brain regions. The spatial arrangement of these electrodes preserves the brain's intrinsic topographic organization. These spatial patterns in EEG data reveal critical insights into emotion-related functional connectivity and neural activation dynamics. It is natural to leverage such patterns to provide auxiliary information for more precise prediction.

Given the input EEG signals $\mathbf{X} \in \mathbb{R}^{N \times C \times B}$, this article first performs spatial projection $\Phi(\cdot)$ based on physical electrode arrangements [38], [43]:

$$\Phi: \mathbb{R}^{N \times C \times B} \rightarrow \mathbb{R}^{N \times B \times H \times W}, \quad \mathbf{S} = \Phi(\mathbf{X}), \quad (7)$$

where \mathbf{S} represents the spatial form of \mathbf{X} . We apply a three-layer CNN encoder to obtain the deep spatial feature \mathbf{Z}_s from \mathbf{S} . To preserve fine-grained spatial resolution, we omit final pooling operation and flatten spatial feature in channel dimension. Finally, the deep spatial feature $\mathbf{Z}_s \in \mathbb{R}^{N \times D}$ is utilized for further fusion.

2) *Cross-view Fusion Mechanism*: The significant inherent intra-subject variance in EEG signals introduces a critical challenge for fusing heterogeneous views. Existing approaches typically process these views independently or employ simple fusion strategies, failing to capture their complex interdependency and potentially introducing feature misalignment. Moreover, inter-subject variability further complicates the fusion since the relationship between the two views may shift across subjects. Drawing inspiration from dynamic fusion strategies [44], [45] in other fields, this article proposes a novel cross-view fusion mechanism that dynamically generates a unified representation from heterogeneous views for unseen subjects, thereby bridging this gap.

To establish space compatibility for cross-view interaction, we apply a learnable transformation to project the spatial feature \mathbf{Z}_s into the semantic space of \mathbf{Z}_g as follow:

$$\widetilde{\mathbf{Z}}_s = \mathbf{W}_{sg}\mathbf{Z}_s + b_{sg}. \quad (8)$$

The aligned representation $\widetilde{\mathbf{Z}}_s$ is then concatenated with \mathbf{Z}_g to form the joint representation $\mathbf{Z}_c = [\widetilde{\mathbf{Z}}_s; \mathbf{Z}_g]$. Then, the cross-view dependencies \mathbf{Z}_Δ between $\widetilde{\mathbf{Z}}_s$ and \mathbf{Z}_g are captured through a multi-head self-attention mechanism formulated as:

$$\mathbf{Z}_\Delta = \mathbf{W}_o \cdot \left[\text{Softmax} \left(\frac{Q_1 K_1^T}{\sqrt{d_h}} \right) V_1; \dots; \text{Softmax} \left(\frac{Q_L K_L^T}{\sqrt{d_h}} \right) V_L \right] \quad (9)$$

where $Q_i, K_i, V_i (l = 1, \dots, L)$ are linear projections of \mathbf{Z}_c . L denotes the number of attention heads. d_h is the dimensionality of key. And \mathbf{W}_o is the learnable projection matrix aggregating the head outputs. The dependencies dynamically recalibrate $\widetilde{\mathbf{Z}}_s$ through residual refinement $\widetilde{\mathbf{Z}}'_s = \widetilde{\mathbf{Z}}_s + \mathbf{Z}_\Delta$. The unified representation \mathbf{Z}_u is obtained through channel-wise concatenation:

$$\mathbf{Z}_u = [\widetilde{\mathbf{Z}}'_s; \mathbf{Z}_g]. \quad (10)$$

To reduce the effect of inter-subject variance in view fusion, we reconceptualize the multi-head self-attention parameters as subject-agnostic meta parameters optimized via model-agnostic meta-learning. These parameters undergo episodic training through model-agnostic meta-learning paradigm [41], enforcing generalization across different subjects through bi-level optimization. Since the few-shot adapter module inherently involves this optimization framework, we will systematically elaborate on the optimization strategy in the subsequent subsection.

D. Few-shot Adapter Module

Acquiring a subject-agnostic unified representation via the CVF module remains insufficient due to the pronounced inter-subject variability in EEG signals. While unified representations provide comprehensive features, they necessitate further refinement to capture discriminative subject-specific emotional patterns. Inspired by adapter-based architectures [46] in CV, this work devises a novel few-shot adapter integrated with meta-learning principles to preserves individualized emotional features.

This article enhances conventional residual adapters through strategic integration of batch normalization layers to statistically regularizes inter-subject variance as follows:

$$\mathcal{A}(\mathbf{Z}_u) = \sigma(\text{BN}(\mathbf{W}_{l2} \cdot \sigma(\text{BN}(\mathbf{W}_{l1}\mathbf{Z}_u)))) + \mathbf{Z}_u, \quad (11)$$

where $\mathbf{W}_{l1} \in \mathbb{R}^{d_h \times d}$ and $\mathbf{W}_{l2} \in \mathbb{R}^{d \times d_h}$ ($d \ll d_h$) enforce a bottleneck for efficient adaptation. The stacked batch normalization layers statistically regularize cross-subject distribution shifts by whitening feature statistics. For clarity, we omit bias terms in Eq.(11). The predicted emotion can be computed using a fully connected layer:

$$\widehat{y} = \text{Softmax}(\mathcal{A}(\mathbf{Z}_u) \cdot \mathbf{W}_c + b). \quad (12)$$

To enable the few-shot adapter to rapidly and effectively capture subject-specific emotional cues, we incorporate MAML's optimization approach [41] into its training. The adapter parameters θ_A are jointly optimized with the multi-head self-attention parameters θ_M and the prediction layer $\theta_{\mathbf{W}_c}$ via bi-level optimization. Our key innovation lies in formulating the adaptation process as a partial meta-learning problem. We treat each subject as a task \mathcal{T} under the MAML paradigm. Since the MAML paradigm follows episodic learning, we randomly sample n subjects per episode for bi-level optimization. For each subject $\mathcal{T}_i \sim p(\mathcal{T})$, we randomly sample a support set \mathcal{D}_i^{sup} and a query set \mathcal{D}_i^{que} . Let the meta-optimized parameters $\Theta = \{\theta_M, \theta_A, \theta_{\mathbf{W}_c}\}$. The whole model parameters $\Theta_{all} = \{\theta_{gcn}, \theta_{cnn}, \Theta\}$ where θ_{gcn} and θ_{cnn} represent the pre-trained weights of the GCN and CNN encoders, respectively. The parameters Θ are optimized to subject-specific parameters Θ'_i via m -steps gradient descent on \mathcal{D}_i^{sup} in the inner loop:

$$\Theta'_i = \Theta - \alpha \nabla_{\Theta} \mathcal{L}_{\mathcal{T}_i}(f_{\Theta_{all}}(\mathcal{D}_i^{sup})) \quad (13)$$

where α the inner-loop learning rate. In this study, we set $\alpha = 0.01$. Through n inner-loop optimizations performed on n subjects, we obtain n sets of subject-specific model parameters. Our objective is to identify an optimal initialization plane that enables efficient convergence to subject-optimal parameters through few-step gradient updates. To achieve this, we should evaluate the performance of inner-loop optimized models while systematically aggregating second-order gradient information across n subjects. This meta-optimization in outer-loop is formally expressed as:

$$\min_{\Theta_{all}} \sum_{\mathcal{T}_i} \mathcal{L}_{\mathcal{T}_i}(f_{\Theta'_{all,i}}(\mathcal{D}_i^{que})). \quad (14)$$

Here, $\Theta'_{all,i} = \{\theta_{gcn}, \theta_{cnn}, \Theta'_i\}$. Notably, the labels of \mathcal{D}_i^{que} is available for the source subjects. The meta-optimization updates whole model parameters through second-order gradients:

$$\Theta'_{all} \leftarrow \Theta_{all} - \beta \nabla_{\Theta_{all}} \sum_{\mathcal{T}_i} \mathcal{L}_{\mathcal{T}_i}(f_{\Theta'_{all,i}}(\mathcal{D}_i^{que})), \quad (15)$$

with $\beta = 0.001$ denoting the outer loop learning rate. The proposed framework yields a subject-agnostic parameter initialization Θ'_{all} through N_e episodes of bi-level optimization during the meta-training phase. The complete training procedure is formalized in Algorithm 1.

During cross-subject evaluation, the proposed framework demonstrates efficient adaptation capability through its meta-learned parameter initialization Θ'_{all} . When encountering novel target subjects S_t , only k -shot labeled EEG samples per class need to be collected as the support set \mathcal{D}_t^{sup} to perform rapid parameter adaptation via inner-loop optimization:

$$\Theta'_t = \Theta - \alpha \nabla_{\Theta} \mathcal{L}(f_{\Theta'_{all}}(\mathcal{D}_t^{sup})). \quad (16)$$

When $k = 3$, the proposed framework achieves performance comparable to state-of-the-art methods.

Algorithm 1 Training Procedure of the Proposed Method

```

1: Initialize  $\Theta_{all} = \{\theta_{gcn}, \theta_{cnn}, \theta_M, \theta_A, \theta_{w_c}\}$ 
2: Set inner-loop learning rate  $\alpha = 0.01$  and outer-loop
   learning rate  $\beta = 0.001$ 
3: for episode  $e = 1$  to  $N_e$  do
4:   Randomly sample  $n$  subjects  $\{\mathcal{T}_1, \mathcal{T}_2, \dots, \mathcal{T}_n\}$  from
   source subject distribution  $p(\mathcal{T})$ 
5:   for  $i = 1$  to  $n$  do
6:     Randomly sample support set  $\mathcal{D}_i^{sup}$  and query set
      $\mathcal{D}_i^{que}$  for subject  $\mathcal{T}_i$ 
7:      $\Theta = \{\theta_M, \theta_A, \theta_{w_c}\}$ 
8:     for  $m = 1$  to  $m$ -steps do
9:        $\Theta'_i = \Theta - \alpha \nabla_{\Theta} \mathcal{L}_{\mathcal{T}_i}(f_{\Theta_{all}}(\mathcal{D}_i^{sup}))$ 
10:    end for
11:     $\Theta'_{all\_i} = \{\theta_{gcn}, \theta_{cnn}, \Theta'_i\}$ 
12:  end for
13:   $\nabla_{\Theta_{all}} \leftarrow \nabla_{\Theta_{all}} \sum_{\mathcal{T}_i} \mathcal{L}_{\mathcal{T}_i}(f_{\Theta'_{all\_i}}(\mathcal{D}_i^{que}))$ 
14:   $\Theta'_{all} \leftarrow \Theta_{all} - \beta \nabla_{\Theta_{all}}$ 
15: end for
16: return  $\Theta'_{all}$ 

```

IV. PERFORMANCE EVALUATION

The benchmarks are described in Section IV-A, followed by a detailed implementation of the proposed approach in Section IV-B. Comparative experimental results with different methods are presented in Sections IV-C1 and IV-C2, respectively.

A. Datasets

This article evaluates the performance of the proposed approach across three well-established EEG emotion recognition benchmarks, including SEED [47], SEED-IV [48], and SEED-V [49]. A detailed description of these benchmarks is provided below:

- **SEED** [47]: The SEED dataset is an EEG emotion recognition dataset collected using the ESI NeuroScan System with a 62-channel electrode cap. It includes data from 15 participants (7 males and 8 females), each participating in 3 sessions approximately one week apart. During each session, participants watched 15 film clips with 3 different emotional tendencies (negative, positive, and neutral), resulting in 45 trials per participant. Following the previous setup, this study employs preprocessed DE features and segments the data into 1-second, non-overlapping sliding windows.

- **SEED-IV** [48]: The SEED-IV dataset is an extended version of the SEED dataset, designed to capture EEG signals induced by videos with 4 emotional tendencies: happiness, sadness, fear, and neutrality. It includes data from 15 participants (7 males and 8 females), each participating in 3 sessions. Consistent with previous work, this study utilizes preprocessed DE features and segments each session into 4-second, non-overlapping sliding windows for further analysis.
- **SEED-V** [49]: The SEED-V dataset is an extension of the SEED-IV dataset, capturing EEG data from 16 participants (6 males and 10 females). Each participant engaged in 3 sessions, with the induced emotional categories expanded to 5 (happiness, sadness, disgust, neutrality, and fear). Consistent with previous setups, this study utilizes preprocessed DE features and segments the data into 4-second, non-overlapping sliding windows for further analysis.

B. Experiment Setup

Network Architecture: This article employs DGCN and Conv-3 as the main backbone. Following previous work [42], the DGCN encoder utilizes a two-layer residual architecture without incorporating K -order Chebyshev polynomials. For this branch, DE features from five frequency bands are concatenated to form the input of size $N \times 62 \times 5$, where N is the number of samples. Conv-3 consists of 3 blocks. Each block contains a 3×3 kernel, a batch normalization layer, a ReLU activation layer, and a 2×2 max-pooling layer. To enable effective spatial learning from EEG signals, the 62-channel DE feature is first projected onto a 2D grid following the physical electrode arrangement on a 9×9 map [38]. This spatial representation is subsequently interpolated to 32×32 resolution. The final input size of the Conv-3 branch is $N \times 32 \times 32 \times 5$.

Evaluation Protocol: This article conducted cross-subject experiments to evaluate the generalization performance of FACE. Following previous studies, this article employed a leave-one-subject-out (LOSO) strategy. In LOSO, each subject serves as the target for testing, while the remaining subjects are used for training. The final performance is reported as the average across all target subjects. Given the few-shot learning paradigm, the model requires a few labeled samples from the target subject. This article randomly shuffles the target subject's samples and selected K samples per class for meta-training, with the remaining samples used for testing. Despite the limited sample size (approximately 1%/5%/8% of samples in SEED/SEED-IV/SEED-V datasets under the 10-shot setting), the proposed method maintains comparability with domain adaptation/generalization-based approaches. To mitigate the risk of overfitting, this article repeated the experiment 200 times for each subject and reported the average performance.

Implementation Details: Recent work has shown that pre-trained models for whole-subject classification have improved the transferability of novel subjects [15]. This article utilizes a two-stage approach involving pre-training and few-shot

TABLE I

\sim indicates an approximation. Since sample amounts vary across subjects, SDDA uses half of the target labeled samples for semi-supervised learning, allowing only an estimation of labeled target samples.

learning for training. For the pre-training stage, this article performs conventional whole-subject emotion classification. The model minimizes the smooth cross-entropy [50] loss across all source subjects under a standard supervised learning scheme. We employ the Adam optimizer with a learning rate 0.001 and train the model from scratch for 50 epochs. After pre-training, the few-shot learning paradigm is adopted. The model is further optimized using the Adam optimizer with a learning rate 0.001 over 50 episodes. For each episode, we randomly sample N subjects. From each subject, $(K + Q)$ samples are randomly selected, where K samples are used for a 10-step fast update, and Q samples are used to evaluate the updated model. The smooth cross-entropy loss is computed across the N subjects to optimize the model, aiming to learn a good initialization that generalizes across all source subjects. In our experiments, N is optimally set to 2, K is chosen from $\{1, 3, 5, 10\}$, and Q is set to 20 during training and to the remaining samples of the target subject during testing. All experiments are implemented using the PyTorch framework and conducted on an AMD Instinct MI250 GPU.

C. Comparison With State-of-the-Art Approaches

This study presents a comprehensive comparison between the proposed method and existing state-of-the-art approaches, including three supervised learning methods (IAG [26],

GMSS [20], and PGCN [19]), three semi-supervised learning methods (SDDA [8], SSML [27], and FSA-TSP [28]), three domain adaptation-based methods (MS-MDA [7], UDDA [8], and Grop [5]), four domain generalization-based methods (GMoE [52], MOGE [34], GDDN [4], and Ugan [33]) and four few shot learning methods (Meta-baseline [7], MMR [35], MAML-EEG [14], and SIML [15]). All experiments were conducted on three widely adopted EEG-based emotion recognition benchmarks (SEED, SEED-IV, and SEED-V). This article reproduced some methods based on open-source code. To ensure fair comparisons and maintain consistency in experimental settings, DGCN was uniformly adopted as the backbone for the few-shot learning methods. Since 5-shot is a widely adopted setting in few-shot learning, most experiments in this article use the 5-shot model as the base. The performance evaluations were carried out on the SEED and SEED-IV benchmarks, as outlined in Section IV-C1, and on the SEED-V benchmark, as detailed in Section IV-C2.

1) *Results on SEED and SEED-IV*: Table I presents a comprehensive comparison of various methods on SEED and SEED-IV datasets. Our method demonstrates competitive performance with state-of-the-art methods. Specifically, FACE achieves an impressive accuracy of 96.72% on SEED and 95.95% on SEED-IV under the 10-shot setting. Furthermore, the proposed method consistently outperforms all competing

TABLE II
COMPARISON WITH STATE-OF-THE-ART APPROACHES ON SEED-V. THE BEST RESULTS ARE SHOWN IN BOLD, AND THE SECOND BEST RESULTS ARE UNDERLINED.

Method	#NUS	#NLS	SEED-V
			Mean / STD (%)
IAG [26]	X	X	59.68 / 9.44
Progressive GCN [53]			71.40 / 9.43
PGCN* [19]			65.21 / 10.10
JAGP [54]	All	X	75.43 / 7.57
GMoE [52]	X	X	76.30 / 9.20
Ugan* [33]			77.12 / 10.87
MoGE [34]			81.80 / 10.00
MetaBaseline* [7]	X	5	85.16 / 5.64
MMR* [35]		5	82.85 / 5.10
SIML* [15]		5	84.88 / 4.59
FACE (Ours)		10	98.95 / 0.36
	X	1	75.74 / 7.00
		3	89.55 / 2.98
		5	<u>95.20 / 1.42</u>
		10	98.95 / 0.36

* denotes the results reproduced through our own implementation based on open-source code.

#NUS refers to the number of unlabeled target samples and #NLS refers to the number of labeled target samples used for training.

approaches in the 5-shot setting, proving the effectiveness of the few-shot learning paradigm and the superiority of the proposed framework. However, the semi-supervised method FSA-TSP exhibits slightly better performance under 3-shot setting compared to our FACE method. This can be attributed to the ability of semi-supervised methods, such as FSA-TSP, to utilize both labeled and large amounts of unlabeled samples during training, thereby improving their performance in low-data scenarios. When the number of labeled samples increases to 5-shot, this performance gap is eliminated. These results demonstrate that while semi-supervised methods benefit from unlabeled data, our approach achieves exceptional performance even with limited labeled data, highlighting the effectiveness of the proposed method in small-sample learning scenarios and its strong generalization capability.

2) *Results on SEED-V*: Since the SEED-V dataset was released only recently, there are relatively few comparative methods available, and the dataset itself is relatively small in scale. Therefore, this article conducts a separate comparative analysis on this dataset and includes additional experiments under the 1-shot setting. Table II demonstrates the effectiveness of the proposed method on the SEED-V dataset. Under the 1-shot setting, the proposed method already achieves competitive performance. Furthermore, in the 3-shot setting, the proposed approach surpasses all other approaches. In the 10-shot setting, the proposed method achieves a high accuracy of 98.95% using only approximately 8% of the labeled target domain samples. These results consistently highlight the superiority and strong generalization of the proposed method in few-shot learning scenarios.

V. DISCUSSION

This section presents a series of ablation studies and visualizations to assess the contribution of each module. Section V-A introduces the module-wise ablation experiments, while Sections V-C and V-B examine the effects of the FSA and CVF modules, respectively. Additionally, Sections V-D and V-E analyze the influence of the number of shots and the hyperparameter L corresponding to the number of attention layers.

A. Module-wise Ablation Study

Table III presents the module-wise ablation studies of the proposed method on the SEED, SEED-IV, and SEED-V datasets. Across different shot settings, incorporating the CVF or FSA module alone generally improves performance compared to the baseline. This demonstrates that subject-specific optimization, whether applied to feature fusion or logit prediction, benefits the model performance. The optimal results are achieved when both CVF and FSA modules are employed. The main reason is that the CVF module provides comprehensive subject-specific features, facilitating more effective adaptation by the FSA module. In this way, the model can learn subject-specific emotional cues more efficiently, thereby improving overall generalization performance.

The statistical analysis in Fig. 3 employs pairwise t-tests to quantify module effectiveness under the 5-shot setting. The asterisk (*) indicates $0.01 < p \leq 0.05$ while the four asterisks (****) denote $p \leq 0.0001$, with a higher number of asterisks representing a more significant improvement. Notably, the consistent presence of multiple asterisks across all datasets confirms that both CVF and FSA components contribute substantially to performance improvement, with p-values falling below 0.0001 in most cases. This evidence highlights the effectiveness of the proposed module.

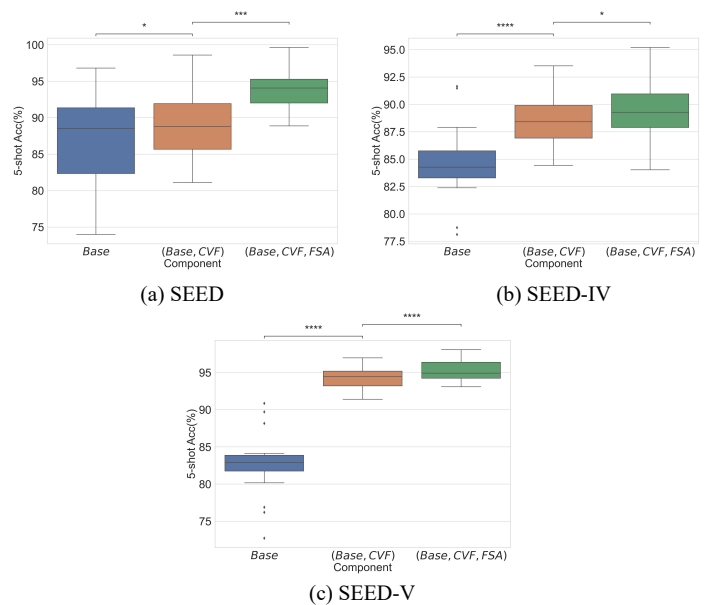

Fig. 3. Statistical comparison of different components on the (a) SEED, (b) SEED-IV, and (c) SEED-V dataset.

TABLE III

ABLATION STUDIES OF THE PROPOSED METHOD ON THE SEED, SEED-IV, AND SEED-V DATASETS, WITH THE BEST RESULTS HIGHLIGHTED IN BOLD.

CVF	FSA	SEED			SEED-IV			SEED-V		
		3-shot	5-shot	10-shot	3-shot	5-shot	10-shot	3-shot	5-shot	10-shot
		81.80±7.79	86.60±6.27	89.70±5.36	80.37±4.33	84.65±3.75	88.21±3.07	78.31±5.23	82.63±4.70	85.20±5.17
✓		90.84±5.26	93.70±3.85	95.36±3.03	82.57±4.44	87.03±3.86	90.73±3.26	87.60±3.80	91.08±3.38	94.63±2.23
	✓	84.51±7.04	88.86±5.48	94.02±3.77	83.48±4.16	88.75±2.74	95.10±1.30	87.81±2.81	94.09±1.58	98.23±0.87
✓	✓	91.66±3.72	93.96±2.70	96.72±1.81	83.91±3.87	89.51±3.13	95.95±1.47	89.55±2.98	95.20±1.42	98.95±0.36

B. Discussion on Impact of CVF module

To rigorously validate the effectiveness of the CVF module, comparative experiments are conducted against conventional fusion strategies across three benchmarks. Table IV, the CVF module demonstrates superior performance by effectively capturing complementary multi-view features, whereas self-attention and cross-attention mechanisms exhibit performance degradation due to inter-view feature distribution incompatibility. This limitation is mitigated through the CVF’s view fusion mechanism, which selectively preserves view-specific discriminative patterns while suppressing inter-modal conflicts. Furthermore, ablation studies reveal a non-negligible performance decline upon removing the meta-learning component implemented via MAML. This empirically validates its critical role in coordinating cross-view feature fusion.

TABLE IV

COMPARISON OF THE CVF MODULE WITH DIFFERENT FUSION ON SEED, SEED-IV, AND SEED-V

	SEED	SEED-IV	SEED-V
Self Attention	78.38±7.91	70.59±7.04	65.62±8.29
Cross Attention	71.91±9.83	59.69±4.98	73.17±9.70
CVF w/o MAML	93.28±4.10	86.58±3.82	90.52±3.42
CVF(ours)	93.70±3.85	87.03±3.86	91.08±3.38

Fig. 4 presents the t-SNE [55] visualization to illustrate the impact of the CVF module on feature representation. The model without the CVF module exhibits substantial inter-class overlap with ambiguous decision boundaries, indicating that the learned feature representations fail to fully distinguish between different emotions. In contrast, integrating the CVF module results in more compact and well-separated clusters, suggesting that CVF enhances the model’s discriminative capability. This improvement is particularly evident in the SEED-IV dataset (Fig. 4 (c) vs. Fig. 4(d)), where the cluster separation and alignment between ground truth markers and predicted colors become more pronounced.

C. Discussion on the Impact of the FSA module

This subsection conducts comparative experiments and visual analysis to investigate the impact of the FSA module. Firstly, this article compares the proposed FSA module with the adaptation methods [46] commonly used in the CV and NLP fields. As demonstrated in Table V, our FSA module

enables more effective subject-specific calibration, resulting in superior performance improvements. Secondly, this article visualizes the brain topographic maps before and after 5-shot adaptation using the FSA module, as illustrated in Fig. 5. Specifically, this article employs the shapley additive global importance [56] to quantify the importance of different channels under various emotional states. The fine-tuned model exhibits highly consistent and similar activated regions under the same emotions across different datasets. Meanwhile, for the negative emotions, the right hemisphere (particularly the right anterior/right prefrontal area) presents more prominent red or warm-colored regions. For neutral emotions, the overall brain region activation distribution appears relatively dispersed without conspicuous highly activated concentrated areas. In addition, positive emotions display stronger activation in the left hemisphere (especially in the left prefrontal lobe activity). These observations are consistent with findings from neuroscience research [57]–[59], thereby validating the effectiveness of the FSA module.

TABLE V

COMPARISON OF THE FSA MODULE WITH DIFFERENT ADAPTERS ON SEED, SEED-IV, AND SEED-V

	SEED	SEED-IV	SEED-V
Linear Probing	84.40±6.57	84.24±4.03	83.64±4.45
Serial Adapter	87.58±5.87	85.11±4.13	84.75±5.44
Residual Adapter	88.09±5.83	86.96±3.46	88.06±3.46
FSA(ours)	88.86±5.48	88.75±2.74	94.09±1.58

D. Discussion on the Impact of the Number of Shot

Fig 6 illustrates the accuracy trends of SEED, SEED-IV, and SEED-V under {1, 3, 5, 7, 9, 10}-shot settings. All three benchmarks demonstrate a consistent improvement in classification accuracy as the number of shots increases. This upward trend suggests that more fine-tuning examples improve the models’ ability to learn discriminative features. When the number of shots reaches 10, the accuracy across all three datasets converges at approximately 99%, indicating that providing 10 labeled samples for fine-tuning is sufficient to achieve promising performance. Moreover, the shaded regions surrounding each performance curve quantify the standard deviation across multiple subjects. The SEED-V dataset achieves superior accuracy and exhibits relatively low variance, which may be attributed to its higher data quality.

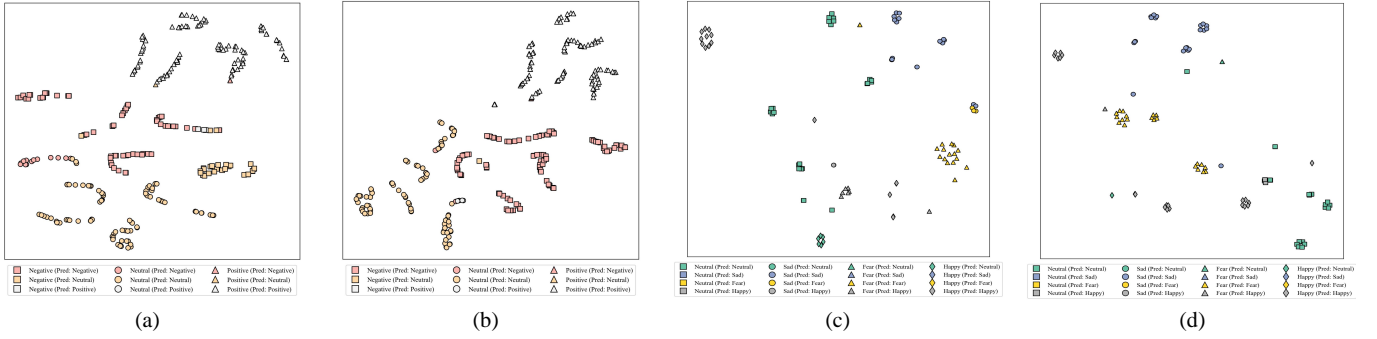

Fig. 4. t-SNE visualization of the SEED and SEED-IV datasets with and without the CVF module under the 5-shot setting. (a) Baseline w/o CVF module on SEED, (b) Baseline w/ CVF module on SEED, (c) Baseline w/o CVF module on SEED-IV, and (d) Baseline w/ CVF module on SEED-IV. Markers represent the ground truth labels, while colors indicate the predicted labels.

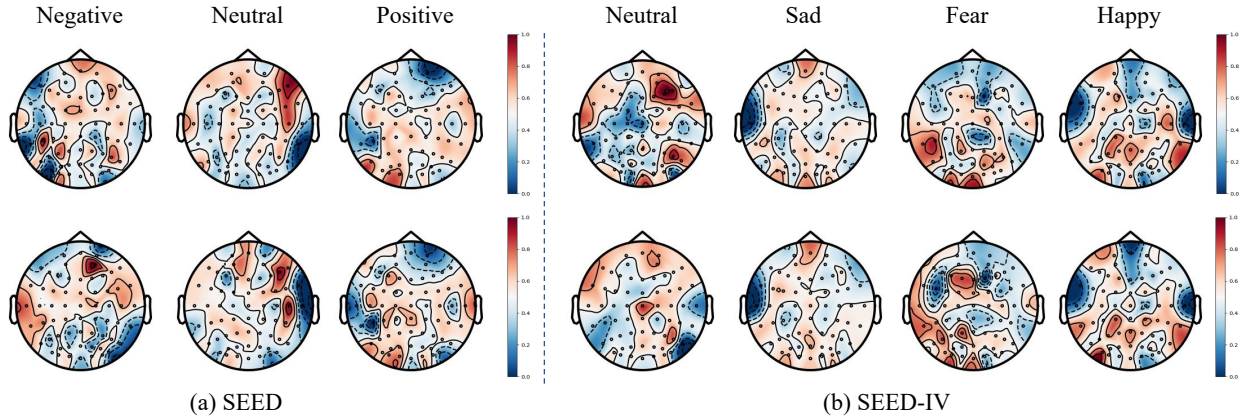

Fig. 5. Brain topographic maps illustrating the effects of 5-shot adaptation on (a) the SEED and (b) the SEED-IV dataset. The first row depicts the state before adaptation, while the second row represents the state after adaptation.

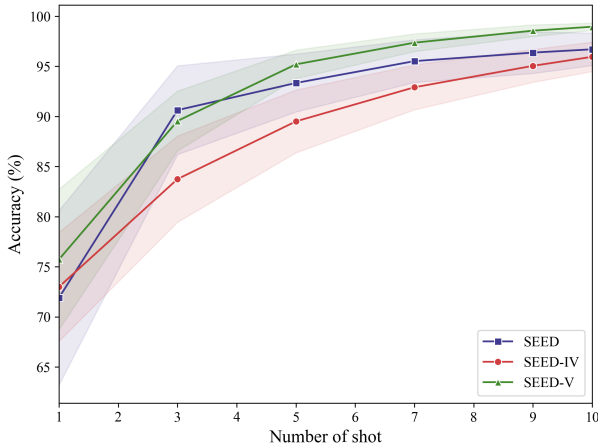

Fig. 6. Accuracy Trends of SEED, SEED-IV and SEED-V across Different Shot Numbers

E. Parameter Sensitivity Analysis

Table VI presents the model performance with different numbers of attention layers (L) across various datasets and few-shot settings. As the number of attention layers changes from 1 to 5 under different shot conditions, the performance shows some fluctuations. However, these changes do not seem to follow a clear upward or downward trend directly related

to the increase in the number of attention layers. Although there are differences between different settings, no significant pattern emerges indicating a strong impact on the number of attention layers. Consequently, these findings suggest that different numbers of attention layers do not produce significant performance variations across the datasets and shot conditions.

TABLE VI
EFFECT OF THE NUMBER OF ATTENTION LAYER

		SEED	SEED-IV	SEED-V
$shot = 3$	$L = 1$	90.63 \pm 4.43	83.75 \pm 4.30	89.55\pm2.98
	$L = 2$	91.66\pm3.72	83.91\pm3.87	89.37 \pm 3.16
	$L = 5$	90.51 \pm 4.52	83.89 \pm 4.26	89.46 \pm 2.72
$shot = 5$	$L = 1$	93.34 \pm 2.89	89.51\pm3.13	95.20\pm1.42
	$L = 2$	93.96\pm2.70	89.30 \pm 2.94	95.09 \pm 1.39
	$L = 5$	93.50 \pm 3.17	89.37 \pm 3.04	95.16 \pm 1.26
$shot = 10$	$L = 1$	96.70 \pm 1.62	95.95\pm1.47	98.86 \pm 0.51
	$L = 2$	96.72\pm1.81	95.87 \pm 1.25	98.91 \pm 0.46
	$L = 5$	96.42 \pm 1.91	95.88 \pm 1.39	98.95\pm0.36

VI. CONCLUSION

This article presented the FACE framework for cross-subject EEG emotion recognition, effectively addressing the challenges associated with inter-subject and intra-subject variance.

The proposed framework demonstrated remarkable capability in capturing subtle emotion-discriminative patterns while mitigating overfitting risks under data scarcity constraints. Specifically, FACE integrated a cross-view fusion module to merge heterogeneous EEG views into a unified representation and a few-shot adapter module to facilitate rapid, subject-specific emotional feature adjustment. Comprehensive experiments on three benchmarks validated the superiority of the proposed method over state-of-the-art approaches. Furthermore, our results demonstrated that fine-tuning with approximately 10 samples per class from a new subject can achieve an emotion classification accuracy of up to 98%. We anticipate this work will inspire further research into few-shot cross-subject BCI interface tasks. Future investigations will focus on few-shot multimodal EEG emotion recognition [60] and extend the few-shot learning paradigm to broader affective BCI applications [61].

Haiqi Liu received the B.S. degree in computer science and technology from South China University of Technology, Guangzhou, China, in 2020. He is currently pursuing the Ph.D. degree in computer science and technology with the School of Computer Science and Engineering.

His research interests mainly include Few shot Learning, Image Recognition and Affective Computing.

C. L. Philip Chen (S'88–M'88–SM'94–F'07) received the M.S. degree from the University of Michigan at Ann Arbor, Ann Arbor, MI, USA, in 1985 and the Ph.D. degree from the Purdue University in 1988, all in electrical and computer science.

He is the Chair Professor and Dean of the College of Computer Science and Engineering, South China University of Technology. He is the former Dean of the Faculty of Science and Technology. He is a Fellow of IEEE, AAAS, IAPR, CAA, and HKIE; a member of Academia Europaea (AE) and European

Academy of Sciences and Arts (EASA). He received IEEE Norbert Wiener Award in 2018 for his contribution in systems and cybernetics, and machine learnings. He is also a highly cited researcher by Clarivate Analytics in 2018, 2019, 2020, 2021 and 2022.

He was the Editor-in-Chief of the IEEE Transactions on Cybernetics (2020–2021) after he completed his term as the Editor-in-Chief of the IEEE Transactions on Systems, Man, and Cybernetics: Systems (2014–2019), followed by serving as the IEEE Systems, Man, and Cybernetics Society President from 2012 to 2013. Currently, he serves as a deputy director of CAAI Transactions on AI, an Associate Editor of the IEEE Transactions on AI, IEEE Trans on SMC: Systems, and IEEE Transactions on Fuzzy Systems, an Associate Editor of China Sciences: Information Sciences. He received Macau FDCT Natural Science Award three times and a First-rank Guangdong Province Scientific and Technology Advancement Award in 2019. His current research interests include cybernetics, computational intelligence, and systems.

Tong Zhang (M'16–SM'24) received the B.S. degree in software engineering from Sun Yat-sen University, at Guangzhou, China, in 2009, and the M.S. degree in applied mathematics from University of Macau, at Macau, China, in 2011, and the Ph.D. degree in software engineering from the University of Macau, at Macau, China in 2016. Dr. Zhang currently is a professor and Associate Dean of the School of Computer Science and Engineering, South China University of Technology, China.

His research interests include affective computing, evolutionary computation, neural network, and other machine learning techniques and their applications. Prof. Zhang is the Associate Editor of the IEEE Transactions on Affective Computing, IEEE Transactions on Computational Social Systems, and Journal of Intelligent Manufacturing. He has been working in publication matters for many IEEE conferences.
