# Abstract

This study examines how AI identity influences psychological empowerment and unethical AI behavior among college students, while also exploring the moderating role of IT mindfulness. Findings show that a strong AI identity enhances psychological empowerment and academic engagement but can also lead to increased unethical AI practices. Crucially, IT mindfulness acts as an ethical safeguard, promoting sensitivity to ethical concerns and reducing misuse of AI. These insights have implications for educators, policymakers, and AI developers, emphasizing For Peer Review the need for a balanced approach that encourages digital engagement without compromising student responsibility. The study also contributes to philosophical discussions of psychological agency, suggesting that empowerment through AI can yield both positive and negative outcomes. Mindfulness emerges as essential in guiding ethical AI interactions. Overall, the research informs ongoing debates on ethics in education and AI, offering strategies to align technological advancement with ethical accountability and responsible use.

**Keywords:** Al identity, psychological empowerment, mindfulness in IT, unethical Al use, higher education, ethical Al behavior, student empowerment, Al in education

### Introduction

Emerging artificial intelligence (AI) technology has a pronounced impact on higher education, addressing existing challenges in educational settings such as larger school sizes and the scarcity of elite instructors. In all these areas, it has been noted that AI has led to massive changes: some estimates suggest that at least 80 percent of workers will have the quantity and quality of at least some of their tasks influenced (for the better) by AI (Canagasuriam & Lukacik, 2024). This means that, in educational contexts, psychological empowerment has been shown to mitigate the combined effects of emotional exhaustion and depression, demonstrating that social relationships and leadership can bolster mental health in institutions (Schermuly & Meyer, 2016). However, this is not to say that AI is without dangers; cybercriminals have also turned to AI to bolster their attacks, for example, in the form of spear phishing or malware installation, showcasing how AI can be abused as a tool to harm enterprises (Mirsky et al., 2023).

Psychological empowerment—comprising meaning, competence, self-determination, and impact—has strong effects on person-environment interactions, which ultimately influence how individuals feel about and perform their jobs (Gregory et al., 2010). Empowered individuals behave differently in projects and, beyond stimulating their senses, tend to be more innovative, contributing to project success and performance (Malik et al., 2021). Moreover, as advances in Al threaten to imperil the professional identities that scientists have come to rely on, they are faced with the obligation to adapt their roles to new technologies (Goto, 2021). This, in turn, suggests that Al identity is likely to be as useful in explaining users' behavior as IT identity or social identity, as demonstrated by cases of obsessive online social gaming (Gong et al., 2021). In education, Al social robots are being used to improve student attention and instructional effectiveness, especially in foreign languages and STEM subjects (Edwards et al., 2019).

Nonetheless, when people feel entitled to technological resources, they are more likely to engage in unethical behavior, particularly if they feel "cheated" by not receiving the special compensations they believe they deserve (Amo et al., 2022). In fact, studies have shown that when people perceive machines as less human-like, moral intent decreases, feelings of guilt lessen, and consequently, their actions become less moral (Giroux et al., 2022). Al robots have been used as teachers, peers, and telepresence instructors to deliver consistent, personalized instruction (Edwards et al., 2019). As the development of machine learning and deep learning algorithms continues to extract increasingly subjective, holistic insights from data and apply them to more personalized learning

experiences, AI devices are becoming more effective and user-friendly (Chi et al., 2022). However, caution is needed in the adoption of AI in education, particularly because the social characteristics of AI teachers, including — or especially — their voice and social presence, may or may not affect learners' perceptions and outcomes (Edwards et al., 2019).

Generative AI, in particular, could be used to transform learning environments into personalized and efficient educational spaces. An AI-powered chatbot called ChatGPT is often able to generate large amounts of tailored text from prompts and, with appropriate training, can debug computer code, generate marketing text, and perform many other tasks (Zhang et al., 2024). Generative AI could reduce working hours without compromising quality; for instance, it might be an affordable way to enhance education (Zhang et al., 2024). Despite these benefits, concerns remain regarding the accuracy and reliability of AI-generated information. Other research has revealed the potential for poorer learning outcomes, as AI-enabled teaching systems may allow inaccuracies to influence learning, which could impact learners' attitudes and behaviors (J. H. Kim et al., 2023). To address this, practitioners ensure that educational content generated by artificial intelligence is error-free by employing mechanisms such as multi-step verification and rewarded feedback (J. H. Kim et al., 2023).

As AI spreads to many more parts of the economy and society—such as education—responses to the issues created by machines that learn (especially when trained in biased ways) will need to be more carefully developed (and analytic philosophy might be called upon to assist). There are important ethical questions surrounding AI and its use in hiring, such as the concern of not replacing subjective decisions with algorithms (Figueroa-Armijos et al., 2023). Furthermore, ethical AI use can help mitigate risks, such as non-compliance with legislation like the General Data Protection Regulation (GDPR), where firms are expected to publicly make an ethical commitment and demonstrate high data security standards (Méndez-Suárez et al., 2023). In the AI4People framework, five basic ethical principles—beneficence, non-maleficence, autonomy, justice, and explicability—are outlined, described as providing a 'human-centric approach' to the development of ethical AI and the protection of human dignity (Bankins & Formosa, 2023). With interpretability issues surrounding investigations of ethical breaches involving AI, accountability must extend beyond individuals to include companies, developers, and sometimes the AI systems themselves (Sullivan & Fosso Wamba, 2022).

The prominent contributions of this work lie in the development of a novel theoretical framework that demonstrates the connection between AI identity, perceptions of psychological empowerment, and ethical conduct, which can help guide educators and policymakers in fostering responsible AI use among students. Although much has been written about AI in education, there are few contextual perspectives or studies that explicitly discuss how students' identification with AI (AI identity) might impact their behavior. Our research will aim to bridge this gap by examining psychological empowerment and mindfulness as variables that may facilitate or inhibit the unethical use of AI in IT. The main contribution of this work lies in offering a new theoretical framework that combines AI identity, psychological empowerment, and moral behavior, which could serve as a practical reference for educators and policymakers to help students develop responsible AI usage.

### Literature Review

### AI and Its Educational Applications

The history of AI in higher education reflects major success and failure. Alan Turing's notion of the 'Turing machine' to describe the general problem of automation (introduced in 1943 and now considered the foundation of AI), and John McCarthy's flagging of 'artificial intelligence' as the 'science and engineering of making intelligent machines' (1956) (Tuo et al., 2024). Although early public interest was sustained, AI alternated between periods of rapid advancement, or 'AI summers,' characterized by unrealistic expectations, and downturns, or 'AI winters,' largely caused by political funding cuts and the failure of AI markets to materialize. However, recent progress in computer vision, speech recognition, and natural language processing has reignited its development (Tuo et al., 2024). In education, AI has been embraced not only as a tool to aid learning or reach new learners but also as a solution to the challenges posed by larger class sizes and teacher shortages (Edwards et al., 2019). Artificial intelligence (AI) also plays a role as robot teachers, among other applications, promising to enhance the quality of instruction, efficiency, and engagement in various subjects, including foreign languages and STEM disciplines (Edwards et al., 2019). These tools, whether teachers, classmates, or telepresence robots, are expected to have broad applicability within educational environments (Edwards et al., 2019).

The integration of AI into education also necessitates careful consideration of its pedagogical implications. For example, students' judgments about AI instructors' social qualities (voice and social presence) and the impact on learning are likely to vary significantly (Edwards et al., 2019). As the efficiency of AI technology continues to rise, it is likely to figuratively occupy even more positions in the classrooms of the future, working as tools for better learning and smarter educational management. Nonetheless, concerns about the ethics of AI use and whether individuals would allow their children to be taught by an AI system rather than a human instructor need continued consideration (Figueroa-Armijos et al., 2023). More generally, the state of AI in higher education is part of a greater educational movement of technological innovation to enhance educational experiences and outcomes.

Generative AI algorithms and tools such as ChatGPT are bringing many positive benefits to education, particularly by improving research and learning. These tools are helping transform education into a contact point where learners can acquire novel capacities in various fields, ranging from hospitality to tourism, which are provided with AI-oriented skills (Dwivedi et al., 2024). A main strength is their capability to offer on-the-fly tailoring of content to human prompts, such as ChatGPT (a large language model-powered tool that generates unique content in response to human prompts), which can be used to generate AI-driven educational content (Zhang et al., 2024). Its ability to produce enormous volumes of bespoke text at great speed allows educators and students to benefit from professional expertise in code debugging, script writing, and marketing content creation. This improves learning while reducing creation time by 40 percent and improving quality by 18 percent (Zhang et al., 2024). Furthermore, tools like text-to-image generators that turn text into visuals and enable users to create original illustrations can add symbolic and memorable value to educational content (Miao & Yang, 2023).

However, despite the clear advantages, Al-based integration into education could lead to the dissemination of unauthentic information as one of its perils. It is easy to see why these text-generating AI systems, offered as they currently are (sometimes even offline), can needlessly deprive our writing of much-needed context or originality (J. H. Kim et al., 2023). Still, the pros of generative AI in education remain substantial: new avenues for engaging with content, improved learning productivity, and boosted creativity in the classroom. Yet these technologies also show promise for improving educational outcomes in the future by providing new tools and pedagogies to teach and learn (Sullivan & Fosso Wamba, 2022).

### **AI Identity**

The idea of AI identity involves how each of us makes sense of and engages with the role of AI in our lives. AI identity is also a role identity, which refers to the self-concept one constructs based on the roles one plays in a social context, intentionally and voluntarily, such as in an academic or work environment (Cao et al., 2023). The positive self-identification of an individual with familiar IT use, which we call "IT identity," can motivate creative IT use and foster fruitful AI engagements (Carter et al., 2020). This is consistent with the theory that people who highly identify with AI might use its capabilities more effectively in academic settings. Identifying with various roles, identity theory posits, helps individuals construct a self-model that, in turn, guides their behavior and their perceptions of the social world around them (Stets & Burke, 2000; Stryker & Burke, 2000). Moreover, in the context of AI, the very mechanism of self-categorization that is instrumental in the formation of AI identity underpins how individuals integrate AI into their professional lives.

Particular identities— in this case, those organized around the fixed role of AI in teaching—can be especially powerful for reducing self-uncertainty. Thus, AI identity bestows upon the user a specific place in well-defined environments and reinforces his or her feeling of competence and power to interact with the machine (Hogg & Adelman, 2013). This identity—personal identity—shapes how one understands oneself and his or her behavior. As role identity theory suggests, an ongoing and proactive process of reasoning (sensemaking) construes a self-view based on cues from one's social environment, driving one's behavior to conform to that identity (Cao et al., 2023).

The development of AI systems that autonomously complete entire work processes threatens professional role identity, as professionals' epistemic latitude (the ability to use knowledge and skill) is curtailed. As a consequence, the actor's self-conception (role identity) is changed by AI (Strich et al., 2021). Such a shift might, in turn, lead to identity threat—the perception that AI poses a threat to their self-entity—and might damage both their self-esteem and threaten professional identity more broadly (Craig et al., 2019). On the other hand, a supportive AI identity (in which workers view AI as a helpful aspect of their job) would decrease AI resistance and enhance job acceptance, stabilizing self-esteem and buffering against identity threats (Mirbabaie et al., 2022). Furthermore, the rarity of AI identity in the workplace can heighten beliefs of uniqueness and entitlement, inflating psychological states that, if left unchecked, could lead to unethical behavior (Cao et al., 2023). This means that AI identity entails not only the social position of AI in people's lives but also the role that an AI agent plays in individuals' self-concept formation on a

psychological level, as well as the impact an AI system's personal interactions have on their professional and personal identity dynamics.

Studies in the field of AI identity indicate both prosocial and antisocial behaviors, although few have direct relevance in school settings. Psychological entitlement-entitlement resulting from a belief in a strong AI identity—can easily lead to unethical behavior, especially when AI identity is perceived as distinctive in the workplace. This uniqueness can magnify feelings of entitlement, thereby increasing the likelihood of unethical actions (Cao et al., 2023). On the other hand, a more positive AI identity might also reduce identity threats and related counter-regulatory behaviors. Therefore, individuals who incorporate AI into their identities might exhibit higher levels of selfesteem and more stable professional selves, which could lead to adaptive behavioral outcomes as well (Mirbabaie et al., 2022). However, the broad adoption of AI systems that perform key professional tasks can challenge professional role identity and negatively impact perceptions of self and job satisfaction, as employees may feel deprofessionalized and dominated by a system that they cannot influence (Strich et al., 2021). In terms of social influence, AI systems can be regarded as similarly "avatar-like" as human experts, influencing users' judgment and decisions, which reflects at least a preliminary degree of acceptance and trust in AI-generated suggestions (Wang et al., 2020). In addition, the disclosure of Al identity can alter consumer behavior. For example, in studies we have conducted, undisclosed AI agents were perceived as more skillful and empathetic than disclosed AI agents, improving efficiency and potentially decreasing unethical behavior relative to the disclosed agents (Li et al., 2024). These studies don't directly apply to students in school, but they do provide insights into how AI identity might affect behaviors when AI is a major element of a setting. This implies that a merging of identities with AI may produce a fractured signal to behavior, depending on context and perception.

#### **Psychological Empowerment in Technology Use**

Psychological empowerment refers to a complex construct that reflects an individual's subjective motivation or personal energy to drive their own initiatives in the workplace. This empowerment is typically associated with feelings of control and influence on the part of the worker. The construct is defined by four core dimensions: competence, meaning, choice (self-determination), and impact. Psychological empowerment climates within organizations are powerful predictors of enhanced individual performance because they nurture autonomy, competence, and meaningfulness within employees' roles (Wallace et al., 2011). This dimension of competence relates to the belief that you

can perform your job effectively, accompanied by a sense of self-efficacy and mastery of your work behaviors (Dust et al., 2014; Mahama & Cheng, 2013). Employee empowerment leads to higher levels of psychological empowerment, including increased intrinsic motivation and task performance, when leaders support and empower their employees (Fong & Snape, 2015). Identity theory suggests that individuals are more likely to perform their jobs well when they perceive themselves as occupying those roles, which in turn makes them feel more competent and autonomous (Stryker & Burke, 2000).

Meaning, another concept that defines psychological empowerment, relates to the congruence (coherence) between the individual's work role and their personal values or ideas about what is important for the specific task (Dust et al., 2014; Mahama & Cheng, 2013). Choice, also known as autonomy or self-regulation, describes a desirable work state characterized by a feeling of autonomy and freedom in regulating one's work behaviors, thereby affording more independence regarding tasks, such as deciding what to do (Dhillon et al., 2020; Dust et al., 2014). Finally, influence concerns perceptions of one's power to impact organizational outcomes or the strategic direction of one's work unit—in other words, feelings of the meaningfulness and significance of one's contributions (Dhillon et al., 2020; Dust et al., 2014). Together, they form a second-order construct, discoverable through factor analyses as discrete but related aspects of the psychological empowerment that exists at an organizational level, where teams and employees are empowered, is associated with increased perceptions of collective competence, autonomy, and meaningfulness, which, in turn, are all linked to better performance outcomes (Craig et al., 2019).

In addition, psychological empowerment can foster intrinsic motivation, ultimately leading to greater task performance, increased organizational citizenship behaviors, and a more proactive orientation toward work (Dust et al., 2014; Iqbal et al., 2020). The involvement of employees is a crucial dimension of work environments that stimulates and mobilizes employees when performing at work (Mahama & Cheng, 2013). Self-efficacy, autonomy, and task-perceived control are crucial for how people engage with new technologies, including education with AI (Spreitzer, 1995). Empowered users not only respond to their work environments but can also assert agency over their role design to better equip themselves for interaction with AI systems (Dust et al., 2018). This promotes thoughtful and responsible technology usage, especially when linked to ethical behavior.

However, this same feeling of agency can cross into ethically dubious areas, especially when people misuse the capabilities of AI. Although empowerment builds responsibility and competence, it can also build entitlement. Students, for example, may abuse AI tools such as ChatGPT for immoral reasons, outsourcing homework or engaging in plagiarism, assuming they can avoid detection or that the end justifies the means (Ouyang et al., 2015). This is the paradox of psychological empowerment, which may be both motivating and morally opaque when power goes unaccountable. For that, tools such as mindfulness in IT are necessary to enable the ethical use of AI and prevent its abuse.

### Unethical Use of AI in Education

The Unethical applications of AI in a variety of fields, such as education, present formidable challenges and ethical problems. Among the most obvious examples of immoral AI practices is programming AI systems to commit fraud, for example, by providing false data to artificially intelligent tax software or by gaming self-checkouts by scanning cheaper barcodes for higher-priced items. This kind of behavior is commonly motivated by a reduced anticipatory guilt when dealing with AI compared to the same number of humans, as individuals find AI systems to lack human-like characteristics and affects (T. Kim et al., 2023). Another unethical use of AI is in the domain of privacy breaches, where AI systems access or change data without permission, resulting in economic losses and moral violations (Chatterjee et al., 2015). Moreover, businesses can use AI applications that lead to bias or violate data protection regulations, such as the GDPR, which require rigorous ethical practices and security (Méndez-Suárez et al., 2023). Biased algorithms in decision-making, such as hiring processes, are also a significant problem that we must address, as they can lead to unjust and discriminatory outcomes (John-Mathews, 2022). These cases illustrate the various unethical uses of AI and underscore the necessity for ethical considerations in the development and deployment of AI technology.

From a pedagogical perspective, the psychology of use serves as a primary motivator for immoral AI applications. Psychological empowerment, such as a sense of self-efficacy and agency, shapes what individuals consider their responsibilities and roles. If ethical leadership with psychological empowerment is capable of improving creativity and moral behavior by aligning individuals' values with the organizational purpose, it can also open the door to immoral activity. Online warnings have been reported, for instance, to deter immoral practices such as cheating (Corrigan-Gibbs et al., 2015). Yet with the presence of AI platforms, things could be very different. The virtual nature of AI

reduces anticipatory guilt, leaving humans feeling less guilty for immoral behavior (T. Kim et al., 2023). Furthermore, psychological entitlement, where deservingness is heightened, can be enhanced through AI interactions, which can lead to further immorality (Cao et al., 2023).

Psychological entitlement, in addition to Al's supposed novelty, can encourage more crimes of dishonesty. Being rare and seen as something special about AI systems can enhance the feeling of entitlement and help individuals rationalize unethical behavior as acceptable in the face of unmet expectations (Cao et al., 2023). This is particularly troubling for decision making – such as in recruitment – where transparency issues within AI frameworks can contribute to feelings of injustice and mistrust. AI systems perceived as untrustworthy and biased can also be exploited for private gain (Figueroa-Armijos et al., 2023). Interpretability of AI judgments becomes especially important, since it can expose or hide moral problems, depending on how transparently the decision-making process of the AI is disclosed to users (John-Mathews, 2022).

These psychological forces play out in educational environments in different ways, such as how AI systems are used to promote one's own ends or how moral norms are broken by an perceived lack of regulation. Students may also exploit AI technologies, like AI writing guides, for immoral activities such as plagiarism. A lack of transparency and accountability on the part of AI systems can further foster such actions. Insights into the psychological motivations behind unethical AI use, including psychological empowerment and entitlement, are key to developing measures to curb them. Moral governance, AI transparency, and a sensibility to psychological processes are critical to supporting ethical AI use in education and beyond.

#### Mindfulness in IT and Ethical Decision-Making

Mindfulness in IT is an IT personality characteristic consisting of greater awareness and sensitivity to present moment perceptions, that has a large impact on one's experience of technology (Thatcher et al., 2018). The term holds particularly true in the case of moral AI use, which encourages an enhanced sensitivity to the consequences of dealing with AI. Mindfulness helps people identify between the positive and negative patterns, which is essential for grappling with the ethical ramifications of AI technologies (Thatcher et al., 2018). By adopting mindfulness into IT, organisations can reduce unethical or addictive use of technologies and promote a more fair and ethical relationship with digital tools (Thatcher et al., 2018). Additionally, mindfulness is a living trait that can be trained for, so organisations can help foster ethical IT use by incorporating

mindfulness into their culture and training initiatives (Thatcher et al., 2018). This relates to a generalisation of mindfulness as an active, receptive response to the present moment that has been shown to lead to greater cognitive and affective outcomes across a wide range of domains, from leisure to the workplace (Creswell, 2017). Thus, training IT to be mindful is a proactive approach towards improving ethical AI use, bringing technology engagements in line with the principles of fairness, transparency and accountability (Cheng et al., 2021).

In doing so, mindfulness promotes moral agency among individuals and organisations. In its prodding toward contemplative interaction with AI systems, mindfulness also allows the subject to think about the moral consequences of his actions. Companies can learn from this by building AI systems that are socially responsible, making them relevant for all users, particularly marginalized and underrepresented groups (Cheng et al., 2021). Such IT-level mindfulness also aids individual users in terms of stress reduction and decision-making, and it can assist in the design of more ethical and equitable AI algorithms. The mindfulness practice can be embedded in organizational training programs as part of a long-term, more responsible approach to fostering a culture that rewards mindful engagement with AI tools for the long-term benefit of society rather than for short-term gains.

Mindfulness in IT is the balance between psychological empowerment and illegitimate AI applications. Psychological empowerment, which increases the sense of competence and self-sufficiency (Spreitzer, 1995), could sometimes also lead to the misuse of AI technologies—such as offshoring jobs or academic obfuscation. However, the more mindfulness people have, the more they're likely to think in the background and consider what the ethical implications of their choices are while navigating AI (Thatcher et al., 2018). Among others, mindfulness acts as a protective layer by allowing users to see what unmoral practices might lead to, and fostering less reckless use of AI technologies. For instance, students in learning environments that are more sensitive to how they engage with AI systems are less likely to resort to unethical acts of plagiarism or misappropriation of AI generated content. Such reflective work acts as a cushion against the possibility that psychological empowerment is itself unethical (Thatcher et al., 2018).

In addition, IT mindfulness fosters an awareness of the longer-term effects of unethical AI usage to foster good and ethical decisions in institutions (Creswell, 2017). If AI is promoted with such a reflective mindset, people are far more likely to consider the wider social impact of their decisions instead of just personal advantage. This psychology of empowerment, coupled with awareness,

fosters a rationalised usage of AI, one that inspires people to take full advantage of AI-enabled technologies while holding fast to their values. The final goal is that the inclusion of mindfulness in IT contributes to an even more ethical and responsible tech culture, in education as well as beyond.

### **Theoretical Framework**

Combining AI identity, psychological empowerment and mindfulness in IT makes for a strong set of assumptions that make ethical decisions about AI use profoundly important. AI identity (defined as the extent to which people identify with AI) contributes to the formation of psychological states and behaviours. An assertive AI identity is potentially coupled with an increase in psychological entitlement, and drives blatant unfaith when individuals view themselves as particular or merited treatment because of their AI expertise or know-how (Cao et al., 2023). This sense of AI individuality as unusual or singular is an additive to that right, a catalyst for unethical behavior. The environment in which AI identity is situated therefore plays an important role in individuals' interactions with AI technologies, and entitlement may drive immorality in high-status or low-status environments (Cao et al., 2023).

Psychological empowerment – which includes an impression of power and competence – can be facilitated or threatened by AI systems, depending on how they shape people's work identities. Workers, for example, who perceive AI as a contribution to their work environment might feel more empowered, potentially inspiring ethical behaviour. In contrast, those who experience AI as a threat to their career are likely to feel disempowered and inclined toward immoral behavior (Strich et al., 2021). This paradox reveals how AI's impact on psychological empowerment is nuanced and hinges on how people think about AI's role in their work. Thus, positive attitudes toward AI could facilitate empowerment and moral decision-making.

Mindfulness in IT is not always explicitly invoked here, but it could be assumed to be a key moderation mechanism that keeps users conscious of their actions and the moral dimensions of their use of AI. For instance, in commercial behavior, disclosing the identity of AI agents lowered social esteem, which is associated with higher unethical behavior (Li et al., 2024). When that's the case, mindfulness training might be used to remind oneself of one's behaviour and make them more ethical by asking them to think about what their behaviour might say about others. As an approach to paying close attention in the moment and fostering ethical engagement, mindfulness might be thus a guard against misappropriation of AI.

Additionally, the moral culture of companies – particularly one that is guided by AI ethics standards – contributes to responsible conduct. Moral structures help workers behave responsibly and grasp the larger consequences of AI choices (Méndez-Suárez et al., 2023). Organizations can support a virtuous cycle of ethical AI by making AI identity, psychological empowerment and mindfulness part of it. This is a model that helps people act ethically toward AI technologies and ensure that what they are doing is within the framework of ethical practices and social values. Ultimately, this combined model reduces unethical behaviour, ensuring a responsible, ethical IT workplace.

# **Research Model and Hypotheses**

Al can be incorporated in teaching, which is both a blessing and a challenge, especially in the area of ethics. To make sense of these problems, this dissertation extends the theoretical frameworks of identity theory, psychological empowerment and mindfulness in IT to address the roles these constructs play in ethical and unethical applications of Al. The suggested research model, depicted below (figure 1), makes Al identity, psychological empowerment and IT mindfulness the main determinants of ethical Al education.

Experimental and observational studies may help illuminate how AI identity can serve as an empowering psychological reality. AI identity refers to the extent to which an individual,

metaphorically, symbolically, and figuratively, incorporates AI into their sense of self. This integration influences their psychological states and workplace behaviors (Cao et al., 2023). Psychological empowerment is a motivating and sustaining personal journey in which an individual learns to derive internal sources of control or motivation in their work environment by enhancing four dimensions of empowerment: meaning, competence, self-determination, and impact (Mahama & Cheng, 2013). Similar to the case of women who believe in perpetual dieting, there is still no direct empirical evidence linking AI identity and psychological empowerment. However, conceptual analyses of the phenomenon provide support for this connection. For instance, employees with a strong AI identity may perceive themselves as more competent, which is likely associated with the competence facet of psychological empowerment (Cao et al., 2023). Internalizing AI into one's work identity can preserve self-worth and decrease identity threats, thereby improving perceptions of personal agency and effect, which are fundamental elements of psychological empowerment (Mirbabaie et al., 2022). Additionally, AI systems can also influence professional role identities, impacting employees' perceptions of their professional identity and capabilities, potentially leading to indirect effects on psychological empowerment (Strich et al., 2021). Although the hypothesis that Al identity enhances psychological empowerment has not been directly tested, the conceptual context outlined here, along with the two empirical studies discussed, supports this connection and encourages further empirical research. Thus, the proposed hypothesis is:

Hypothesis 1 (H1): Al identity has a positive effect on psychological empowerment.

The links between psychological empowerment and the ethical use and/or misuse of AI can be understood through the lens of psychological entitlement and its behavioral consequences. Psychological empowerment, which includes fostering positive self-efficacy and greater decision latitude, typically leads to cognitive conditions that encourage ethical leadership behavior and creativity (Javed et al., 2017). However, when psychological empowerment fosters entitlement, it can lead to immoral behavior. This entitlement—characterized by elevated self-esteem and a demand for special treatment—can drive individuals to commit immoral acts in order to fulfill their perceived needs (Cao et al., 2023). In the case of AI, this might result in abuses of AI technologies, with entitled individuals using AI devices for self-serving purposes or to violate norms. Perceptions of AI as non-humans can also amplify this effect, as individuals experience less anticipatory guilt when interacting with AI than with humans, which increases unethical behavior (T. Kim et al., 2023).

There is even evidence that this tendency toward immorality escalates when dealing with AI compared to human agents because people feel less emotional and moral concern (T. Kim et al., 2023). Although psychological empowerment can encourage beneficial outcomes like creativity, it can also foster rogue AI if it promotes entitlement without sufficient ethical monitoring. This underscores the need for a balance between empowerment and ethical training and reporting to reduce immoral activity in AI tools. Hence,

**Hypothesis 2 (H2):** Psychological empowerment has a positive effect on unethical use of AI.

IT mindfulness is a term used to describe an individual's skill in acting in a conscious and responsive manner regarding their technology use, monitoring their thoughts, emotions, and actions as they interact with IT systems (Thatcher et al., 2018). If someone has a strong AI identity, it may even feel psychologically empowering because they have an understanding and belief in AI. However, high levels of IT mindfulness can mitigate this sense of agency by prompting individuals to critically assess how they use AI tools. The practice of mindfulness enhances our awareness of ethical implications and potential drawbacks, encouraging a more balanced use of AI. Mindfulness is therefore a regulating variable, cooling the tension between AI identity and psychological agency. Students who are aware of their AI usage are less likely to experience unregulated empowerment that might lead to hyper-confidence or unethical conduct. Instead, mindfulness encourages a reflective and cautious approach to AI, minimizing the risk of AI overidentification and promoting more informed uses of these technologies (Thatcher et al., 2018). Thus, the proposed hypothesis is:

**Hypothesis 3a (H3a):** Mindfulness in IT negatively moderates the relationship between AI identity and psychological empowerment.

Mindfulness in IT helps balance the divide between psychological empowerment and immoral AI. Although psychological empowerment promotes autonomy and self-control, it can also encourage unethical behavior when individuals are overly confident or feel entitled to misuse AI for personal purposes, such as outsourcing homework or engaging in academic cheating (Spreitzer, 1995). However, IT mindfulness helps counteract this threat through moral reflection and understanding. The more mindful students are in their AI use, the more aware they will be of the long-term consequences of their actions—such as the ethical implications of cheating or plagiarizing with AI (Thatcher et al., 2018). Mindfulness encourages us to align our actions with broader ethical

expectations, helping to minimize the possibility of unrighteous behavior. By increasing awareness of the risks, IT mindfulness also ensures that through psychological empowerment, we will use AI purposefully rather than with impunity (Creswell, 2017). This moderating effect highlights the importance of developing mindfulness in educational settings where AI tools are increasingly integrated, aiding students in navigating the existential questions these technologies raise. Hence:

**Hypothesis 3b (H3b):** Mindfulness in IT negatively moderates the relationship between psychological empowerment and unethical use of AI.

### Methodology

We use a questionnaire to evaluate business school students' perceived AI willingness attitudes and beliefs based on existing, validated scale constructs adapted to our study setting (Appendix 1). More specifically, psychological empowerment, in the sense defined by Spreitzer, (1995), is a second-order phenomenon: competence, meaningfulness, impact, and choice. For example, psychological power is defined as importance, ability, influence, and control (Spreitzer, 1995). This second-order understanding of psychological empowerment has been studied and tested in the literature to date, such as in Dhillon et al., (2020). Each non-demographic question was scaled using a five-point Likert scale (1 = 'Strongly disagree', 5 = 'Strongly agree').

These respondents were selected from an online panel offered by Qualtrics and ranged across multiple demographic groups. The survey instrument was accessed by 282 students, and 240 of the responses met the criteria for error-free completion. To ensure a respondent profile that accurately reflected what was realistically available, we included screening questions as stipulated for the study. Participants were excluded if they lacked prior experience using ChatGPT or other AI tools, or if they completed the survey in under 5 minutes (a time baseline that was pre-tested).

### Data Analysis

Data analysis was conducted using partial least squares-based structural equation modeling (PLS-SEM) with Smart-PLS 4.0.9 and SPSS software (Ringle, 2005). This approach was chosen for two reasons: 1) PLS-SEM is particularly suitable for modeling endogenous constructs, and 2) it aligns well with the exploratory nature of the results presented in this study. Additionally, PLS-SEM offers several advantages over the CB-SEM approach by avoiding numerous limiting assumptions. It

demonstrates robustness issues such as skewed distributions and omitted regressors, and residual distributions (Cassel et al., 1999).

Data analysis followed a two-step procedure as outlined by Anderson & Gerbing (1988a). Initially, the measurement model underwent examination to establish the reliability and validity of the constructs. Subsequently, the structural model was analyzed to assess predictive relevance, effect magnitudes, and variance explained.

#### Demographics

In Table 1, the demographic information reveals that the respondent pool comprised 51.6% male and 47.3% female participants, with the majority (67.97%) falling between the ages of 18-24 years old. The remaining 32.8% of the participants were 25 years of age or older.

Table 1: Demographics										
Age		Gender		Race		Education				
18-24	67.97%	Male	51.56%	White or Caucasian	31.64%	Some high school or less	0.78%			
25 - 34	21.88%	Female	47.27%	Black or African American	6.64%	High school diploma or GED	6.25%			
35 - 44	7.42%	Prefer Not to Say	1.17%	American Indian / Native American or Alaska Native	1.56%	Some college, but no degree	17.97%			
45 – 54	1.95%			Asian	48.44%	Bachelor's degree	51.95%			
55 - 64	0.78%			Native Hawaiian or Other Pacific Islander	0.00%	Graduate or professional degree	14.06%			
Over 65	0.00%			Other	8.98%	Associates or technical degree	8.98%			
				Prefer Not to Say	2.73%	Prefer Not to Say	0.00%			

#### Measurement Model

Table 2 presents the results of factor loadings, Cronbach alphas, composite reliabilities, average variance explained (AVE), and factor correlations. All factor loadings surpass 0.76, exceeding the 0.70 threshold, demonstrating robust discriminant validity. The Cronbach alpha coefficients exceed 0.88, surpassing the 0.70 threshold, signifying strong internal validity. Moreover, the composite reliability values are higher than 0.93, indicating satisfactory internal consistency. The AVE values are greater than 0.7, confirming strong convergent validity, as recommended by Hair, J., Black, W., Babin, B. and Anderson (2010).

The square root of the Average Variance Extracted (AVE) in the factor correlation matrix indicates satisfaction of the Fornell-Larcker criterion, as the diagonal elements are all greater than the loadings for the other latent variables. This finding signifies strong discriminant validity (Fornell & Larcker, 1981). Figure 2 presents the Heterotrait-Monotrait Ratio (HTMT) results, where it is evident that all the relationships between latent variables are below 0.84, providing strong evidence of discriminant validity (Henseler et al., 2015).

Table 2: Reliability, validity, and factor correlations

#### Common Method Variance

To minimize the effects of CMV, the study design was carefully considered (Conway & Lance, 2010; Podsakoff et al., 2003). Three researchers reviewed the questionnaire for words and phrasing that could prevent ambiguity. Moreover, the order of the questionnaire items was arranged to limit carryover effects from context (Podsakoff et al., 2003). Lastly, contextual shifts were created to induce psychological distancing between sets of objects, according to Craighead et al. (2011). Second, a marker variable was included to help control for the possibility of inflated common method variance (CMV). Further, advanced respondents received the promise that individual responses would be reported only in aggregate, with no data collected on individual identity. This approach effectively reduces evaluation apprehension, thereby further mitigating method bias (Conway & Lance, 2010).

We used Harman's one-factor test as an indicator of common method variance (CMV) – that is, if CMV is present, one factor will dominate or one general factor will, in general, explain a large portion of variance (Harman & Harman, 1976). An exploratory factor analysis with varimax rotation revealed that the first factor accounted for only 21.20% of the variance, and when considering all seven factors combined, they explained 82.74% of the total variance. These results indicate the

absence of a dominant general factor, suggesting that CMV is unlikely to have significantly influenced our findings.

### Structural Model

Figure 3 presents the structural model, depicting path coefficients, significance levels, and Rsquared values. The model proposed in this study accounts for 36% of the variance associated with Unethical use of ChatGPT and 31% of the variance associated with psychological empowerment. Both main effects were statistically significant, as well as both of the moderating effects.

The study's findings indicate that AI identity (H1) positively influences psychological empowerment. Furthermore, psychological empowerment (H2) was found to have a positive impact on the unethical use of ChatGPT. Concerning the moderating effects, both were observed to be statistically significant. Specifically, IT Mindfulness was found to negatively moderate the relationship between AI Identity and psychological empowerment (P-value <0.05, as shown in Figure 4). Additionally, IT Mindfulness also negatively moderates the relationship between psychological empowerment and unethical use of ChatGPT (P-value <0.05, as depicted in Figure 5).

### Discussion

This study investigated the relationships between AI identity, psychological empowerment, mindfulness in IT, and the unethical use of AI in higher education. The results revealed that AI identity was positively associated with psychological empowerment, and psychological empowerment predicted unethical uses of AI technologies.

Meanwhile, mindfulness in IT negatively moderated both the relationship between AI identity and psychological empowerment, as well as the link between psychological empowerment and unethical AI use.

The outcomes indicate that individuals who identify more strongly with Al—viewing it as a central part of their academic and professional lives—feel more empowered to use AI technologies. Empowering students in this manner fosters confidence and a sense of efficacy, helping them recognize how AI in the classroom can support their learning goals. However, it also poses the possibility of confirmation bias, which could promote immoral practices—from the misuse of AI devices for cheating (including plagiarism) to assigning tasks to artificial intelligence.

The results make it even more crucial that IT mindfulness plays a role in reducing the risks associated with AI identity and psychological empowerment. High-Memory students are encouraged to approach the AI software more kindly. They are asked to determine what the morally permissible option would be, despite acknowledging that they are using the technology at their own risk. Although psychological empowerment can encourage overconfidence, mindfulness can restrain this by prompting users to question their AI-use decisions and thus steer clear of unethical behavior. Not only do AI identities facilitate psychological empowerment and academic engagement, but they also enable students and educators to experience greater health and wellness through ethical and responsible AI use. The intersection of Artificial Intelligence in Education and Positive Psychology promotes learning and well-being for all stakeholders involved (Bittencourt et al., 2023).

This helps explain why AI, when used responsibly, can be a powerful force for good in education, as well as why it can have negative effects. They also argue that, alongside the benefits AI identity and psychological empowerment can provide in enhancing students' engagement and performance, there is also a potential for significant ethical risks if these factors are mismanaged.

### Implications

Given the results, universities and educators should not only promote the use of AI in learning but also encourage students' mindfulness in IT from an early stage. By doing so, institutions can instill mindfulness that will stay with students as they continue to use these technologies in science and industry, increasing the likelihood that they will use AI tools ethically rather than carelessly. Mindfulness training or IT workshops might be added to training to support ethical AI decision making.

This research could be valuable for the creators of educational AI tools. It encourages consideration of students' understanding and use of AI and the development of AI systems for thoughtful application. One possible outcome might be an ethics warning or a log of how many times a student has used a digital assistant, such as AI-C, prompting students to reflect more critically on its usage.

These findings provide a starting point for examining how AI identity and psychological empowerment function in different educational settings, including various professional environments outside of higher education. The study could also explore long-term bias reductions by incorporating mindfulness instruction into IT courses through a before-and-after study to test whether and how effectively it systematically eliminates unethical AI usage among students.

Institutions strive to create environments where students are comfortable with AI while keeping their consciences attuned to its ethical limits. Achieving this is challenging, but it can be done through a moralizing approach to the technology, fostering a culture of moral scrutiny, and incorporating tools and models (including the mindfulness model) into academic AI research. Additionally, institutions can work to correct any misconceptions that democratization through AI tools justifies students 'cheating' in their academic work.

### Conclusion

This qualitative study investigated the grey areas that exist between and among AI identity, psychological empowerment, sensation seeking, mindfulness, and the criminal and unethical use of AI in higher education. The results highlight the dual nature of psychological empowerment,

which can foster purposeful and positive engagement with AI but also fuel unethical behavior in the absence of appropriate checks. This remains true even when a very strong AI identity underpins individuals' academic and professional identities, acknowledging both the advantages of empowerment and the risks of overconfidence or abuse in the deployment of AI tools.

Mindfulness was a key moderating factor; for example, IT mindfulness attenuated the impact of AI identity and psychological empowerment. Those students scoring higher on mindfulness were more likely to adopt a reflective and ethical approach to AI use, which significantly reduced the odds of unethical behavior. This implies that cultivating mindfulness in IT can become a useful strategy for counterbalancing some of the possible ethical hazards of AI in education. In keeping with identity theory, those who strongly identify with AI technologies might behave in ways consistent with their 'perceived role as powerful AI users' and this could impact both ethical and unethical behaviour (Stryker & Burke, 2000).

Encouraging our children to be technologically engaged while also promoting ethical responsibility within the human community is vital and must be addressed in curricula. By incorporating mindfulness into IT training, responsible AI use can be fostered. Indeed, students will not only maximize the benefits of available AI tools but also cultivate the courage to confront emerging ethical dilemmas. Moving forward, future research should aim to deepen the understanding of how AI identity and psychological empowerment interrelate across diverse contexts and consider the long-term outcomes regarding the ethical use of AI following the cultivation of mindfulness in learning and work.
