Abstract

We present a variational integrator based on the Lobatto quadrature for the time integration of dynamical systems issued from the least action principle. This numerical method uses a cubic interpolation of the states and the action is approximated at each time step by Lobatto's formula. Numerical analysis is performed on a harmonic oscillator. The scheme is conditionally stable, sixth-order accurate, and symplectic. It preserves an approximate energy quantity. Simulation results illustrate the performance of the proposed method.

^{*} This contribution has been submitted to the 7th International Conference on *Geometric Science* of Information, Saint-Malo, 29-31 October 2025.

1) Introduction

A well-known geometric property of Hamiltonian systems is that their flows preserve the phase space volume, a Poincaré invariant. However, integrable Hamiltonian systems are rare. Numerical methods are usually required to find solutions. By generating functions of canonical transformations, symplectic variants of standard integrators can be achieved. We refer *e.g.* to the symplectic Euler or Runge-Kutta [5], or the implicit midpoint scheme that coincides with the average constant acceleration Newmark variant for linear systems. This method was proposed by J.C. Simo [10] and is symplectic for both the linear and nonlinear cases. However, a good way to embed the natural geometry of Hamiltonian systems into an integrator is to start with the variational principle of least action.

In this contribution, we first recall the Lobatto quadrature scheme in Section 2. Section 3 presents the selected interpolation of functions with finite elements. Then, starting with the least action principle, the Lobatto integrator is developed on the harmonic oscillator in Section 4. The resulting scheme is expressed as a variant of the implicit midpoint integrator [10] and the Simpson integrator proposed in [2]; it is a special case of the Galerkin methods introduced in [6]. The symplectic structure of the Lobatto integrator is analyzed at the end of Section 4. The method preserves a discrete Hamiltonian as remarked by [1]. Some numerical results are presented in Section 5 before some conclusive words.

2) Lobatto's Quadrature

Let us consider the Lobatto quadrature [4] with two internal control points. It requires three coefficients α , β and ξ such that

(1)
$$\int_0^1 f(t) dt \approx \alpha(f(0) + f(1)) + \beta(f(\xi) + f(1 - \xi)).$$

If $\xi = \frac{1}{2}$, Simpson's quadrature is found [2, 3, 8]. Let us then suppose that $0 < \xi < \frac{1}{2}$ so that two internal control points are satisfied. When f(t) = 1 or f(t) = t, the quadrature (1) leads to the restriction that $\alpha + \beta = \frac{1}{2}$. When $f(t) = t^2$, we have $\alpha + \beta (1-2\xi+2\xi^2) = \frac{1}{3}$, so $\beta \xi (1-\xi) = \frac{1}{12}$. When $f(t) = t^4$, we have $\beta \xi (1-\xi)(\xi^2-\xi+2) = \frac{3}{10}$, and by recalling the value of $\beta \xi (1-\xi)$, the internal control point can be solved using $\xi (1-\xi) = \frac{1}{5}$. The parameters α and β are obtained by applying the value of ξ on $\beta \xi (1-\xi) = \frac{1}{12}$: $\xi = \frac{1}{2} - \frac{\sqrt{5}}{10}$, $\alpha = \frac{1}{12}$, $\beta = \frac{5}{12}$. Therefore, the proposed Lobatto quadrature is

(2)
$$\int_0^1 f(t) dt \approx \frac{1}{12} \left(f(0) + f(1) \right) + \frac{5}{12} \left(f(\xi) + f(1-\xi) \right), \qquad \xi = \frac{1}{2} - \frac{\sqrt{5}}{10}$$

Lobatto's quadrature (2) is accurate for polynomials up to degree 2n - 3, where *n* is the number of integration points. In the present case n = 4, so the proposed Lobatto quadrature is exact for the integration of polynomials up to degree five This can be easily verified using the obtained values of α , β and ξ .

A VARIATIONAL SYMPLECTIC SCHEME BASED ON LOBATTO'S QUADRATURE

3) Cubic Interpolation

Lagrange's P_3 polynomials [4] are selected for the finite-elements-based internal interpolation of a time interval [0, h], where h is the step size. For $0 \le \theta \le 1$, the following four basis functions

(3)
$$\begin{cases} \varphi_0(\theta) = 5(\theta - \xi) \left(\theta - (1 - \xi)\right) \left(1 - \theta\right) \\ \varphi_{\xi}(\theta) = -5\sqrt{5} \theta \left(1 - \theta\right) \left(\theta - (1 - \xi)\right) \\ \varphi_{1-\xi}(\theta) = 5\sqrt{5} \theta \left(1 - \theta\right) \left(\theta - \xi\right) \\ \varphi_{1}(\theta) = 5\theta \left(\theta - \xi\right) \left(\theta - (1 - \xi)\right) \end{cases}$$

evaluate to 1 when the control point is the same as the index and 0 at the other integration points.

Taking $t = h\theta$, where h is the step size, one can build a function $t \mapsto q(t)$ on the interval [0, h] using the above P_3 finite elements:

$$q(t) = q_{\ell} \varphi_0(\theta) + q_{\xi} \varphi_{\xi}(\theta) + q_{1-\xi} \varphi_{1-\xi}(\theta) + q_r \varphi_1(\theta).$$

This is a vectorial and third-order function on [t, t+h]. Note that $q(0) = q_{\ell}$, $q(\frac{h}{2} - \frac{\sqrt{5}h}{10}) = q_{\xi}$, $q(\frac{h}{2} + \frac{\sqrt{5}h}{10}) = q_{1-\xi}$, and $q(h) = q_r$ so the basis functions (3) are well adapted to the chosen quadrature. The time derivative is a second-order polynomial concerning θ :

$$\frac{\mathrm{d}q}{\mathrm{d}t} = \frac{1}{h} \left[q_\ell \,\varphi_0'(\theta) + q_\xi \,\varphi_\xi'(\theta) + q_{1-\xi} \,\varphi_{1-\xi}'(\theta) + q_r \,\varphi_r'(\theta) \right].$$

4) The Harmonic Oscillator Case

Let us consider a dynamical system described by a state q(t) which is a single real variable for $0 \le t \le T$. The continuous action S_c introduces a Lagrangian quantity L and is defined by

(4)
$$S_c = \int_0^T L\left(\frac{\mathrm{d}q}{\mathrm{d}t}, q\right) \mathrm{d}t$$

For the harmonic oscillator, the Lagrangian is $L\left(\frac{dq}{dt}, q\right) = \frac{m}{2} \left(\frac{dq}{dt}\right)^2 - V(q)$, where the terms on the right are the kinetic and potential energies, in said order. The action (4) is discretized by splitting the time interval [0,T] into N elements of equal length $h = \frac{T}{N}$. The approximation q_j of $q(t_j)$ will be given at each discrete time instance $t_j = j h$.

• Discrete Lagrangian

Using the Lobatto quadrature (2), the kinetic energy is viewed as an integral function:

$$K_d = \frac{1}{h} \int_0^h \frac{1}{2} m \left(\frac{\mathrm{d}q}{\mathrm{d}t}\right)^2 \mathrm{d}t = \frac{1}{2} m \int_0^1 \left(\frac{1}{h} \frac{\mathrm{d}q}{\mathrm{d}\theta}\right)^2 \mathrm{d}\theta$$

by changing the integration variable. A symmetric quadratic form emerges as

$$K_d = \frac{m}{2h^2} \left(\alpha \left[\left(\frac{\mathrm{d}q}{\mathrm{d}\theta}(0) \right)^2 + \left(\frac{\mathrm{d}q}{\mathrm{d}\theta}(1) \right)^2 \right] + \beta \left[\left(\frac{\mathrm{d}q}{\mathrm{d}\theta}(\xi) \right)^2 + \left(\frac{\mathrm{d}q}{\mathrm{d}\theta}(1-\xi) \right)^2 \right] \right).$$

Then $K_d \equiv \frac{m}{2h^2} q_{\theta}{}^{\mathrm{t}} K q_{\theta}$, where $q_{\theta} = (q_0, q_{\xi}, q_{1-\xi}, q_1)^{\mathrm{t}}$ and

$$K = \begin{pmatrix} \frac{13}{3} & -\frac{5\sqrt{5}}{4} - \frac{25}{12} & \frac{5\sqrt{5}}{4} - \frac{25}{12} & -\frac{1}{6} \\ -\frac{5\sqrt{5}}{4} - \frac{25}{12} & \frac{25}{3} & -\frac{25}{6} & \frac{5\sqrt{5}}{4} - \frac{25}{12} \\ \frac{5\sqrt{5}}{4} - \frac{25}{12} & -\frac{25}{6} & \frac{25}{3} & -\frac{5\sqrt{5}}{4} - \frac{25}{12} \\ -\frac{1}{6} & \frac{5\sqrt{5}}{4} - \frac{25}{12} & -\frac{5\sqrt{5}}{4} - \frac{25}{12} & \frac{13}{3} \end{pmatrix}$$

When the potential energy function $q \mapsto V(q)$ is a polynomial of degree ≤ 5 , the quadrature (2) integrates it accurately and

$$U \equiv \frac{1}{h} \int_0^h V(q(t)) \, \mathrm{d}t = \alpha [V(q_0) + V(q_1)] + \beta [V(q_\xi) + V(q_{1-\xi})].$$

In this example, the potential energy function is $V(q) = \frac{1}{2}m\omega^2 q^2$. The discrete Lagrangian $L_d \equiv h(K_d - U)$, can be expressed as a function of the degrees of freedom within the interval [0,h]: $q_\ell = q(0)$, $q_\xi = q(\xi h)$, $q_{1-\xi} = q((1-\xi)h)$, and $q_r = q(h)$. The Lagrangian $L_d \equiv L_d (q_\ell, q_\xi, q_{1-\xi}, q_r)$ is given by

(5)
$$L_{d} = \begin{cases} \frac{m}{12h} \left[26 \left(q_{\ell}^{2} + q_{r}^{2} \right) - 2 q_{\ell} q_{r} + 50 \left(q_{\xi}^{2} - q_{\xi} q_{1-\xi} + q_{1-\xi}^{2} \right) \right. \\ \left. - 25 \left(q_{\ell} + q_{r} \right) \left(q_{\xi} + q_{1-\xi} \right) - 15 \sqrt{5} \left(q_{\ell} - q_{r} \right) \left(q_{\xi} - q_{1-\xi} \right) \right] \\ \left. - \frac{m \hbar \omega^{2}}{24} \left[q_{\ell}^{2} + q_{r}^{2} + 5 \left(q_{\xi}^{2} + q_{1-\xi}^{2} \right) \right]. \end{cases}$$

The internal degrees of freedom q_{ξ} and $q_{1-\xi}$ are eliminated by solving the system formed by the discrete Euler-Lagrange equations inside the interval, that is

$$\frac{\partial L_d}{\partial q_{\xi}} = 0, \qquad \frac{\partial L_d}{\partial q_{1-\xi}} = 0.$$

The explicit expressions of q_{ξ} and $q_{1-\xi}$ are

(6)
$$\begin{cases} q_{\xi} = \frac{1}{\delta} \left[-5 \left(h^2 \omega^2 - 30 \right) \left(q_r + q_{\ell} \right) + 3\sqrt{5} \left(h^2 \omega^2 - 10 \right) \left(q_r - q_{\ell} \right) \right] \\ q_{1-\xi} = \frac{1}{\delta} \left[-5 \left(h^2 \omega^2 - 30 \right) \left(q_r + q_{\ell} \right) - 3\sqrt{5} \left(h^2 \omega^2 - 10 \right) \left(q_r - q_{\ell} \right) \right] , \end{cases}$$

with a determinant

(7)
$$\delta = (h^2 \omega^2 - 30) (h^2 \omega^2 - 10) > 0 \quad \text{for} \quad 0 < h\omega < \sqrt{10}$$

indicates conditional stability. By using the expressions of equations (6) within the discrete Lagrangian (5), a reduced Lagrangian $L_r(q_\ell, q_r)$ is revealed:

$$L_{r} = \begin{cases} \frac{1}{6 h \delta} \left[\frac{m}{4} \left(-h^{6} \omega^{6} + 92 h^{4} \omega^{4} - 1680 h^{2} \omega^{2} + 3600 \right) \left(q_{\ell}^{2} + q_{r}^{2} \right) \\ -m \left(h^{4} \omega^{4} + 60 h^{2} \omega^{2} + 1800 \right) q_{\ell} q_{r} \right]. \end{cases}$$

• Euler-Lagrange Equations

A discrete form S_d of the continuous action S_c (4) involves the reduced Lagrangian:

$$S_d = \sum_j L_r(q_j, q_{j+1}) \,.$$

It is stationary with respect to the internal degree of freedom q_j when $\frac{\partial S_d}{\partial q_j} = 0$. This leads to the discrete Euler-Lagrange equations

(8)
$$\frac{\partial}{\partial q_{\ell}} L_r(q_{j-1}, q_j) q_r + \frac{\partial}{\partial q_r} L_r(q_j, q_{j+1}) q_{\ell} = 0,$$

A VARIATIONAL SYMPLECTIC SCHEME BASED ON LOBATTO'S QUADRATURE

which become

(9)
$$\begin{cases} \frac{1}{h^2} (q_{j-1} - 2q_j + q_{j+1}) + \frac{\omega^2}{30} (q_{j-1} + 28q_j + q_{j+1}) \\ + \frac{\omega^4 h^2}{1800} (q_{j-1} - 92q_j + q_{j+1}) + \frac{\omega^6 h^4}{1800} q_j = 0. \end{cases}$$

The truncation order is obtained by replacing the discrete variables q_{j+1} , q_j and q_{j-1} by the solution of the differential equation at $t_j + h$, t_j and $t_j - h$. Then

$$\begin{cases} q_{j+1} = q_j + h \frac{\mathrm{d}q}{\mathrm{d}t} + \frac{h^2}{2} \frac{\mathrm{d}^2 q}{\mathrm{d}t^2} + \frac{h^3}{6} \frac{\mathrm{d}^3 q}{\mathrm{d}t^3} + \frac{h^4}{24} \frac{\mathrm{d}^4 q}{\mathrm{d}t^4} + \frac{h^5}{120} \frac{\mathrm{d}^5 q}{\mathrm{d}t^5} + \frac{h^6}{720} \frac{\mathrm{d}^6 q}{\mathrm{d}t^6} + \mathcal{O}(h^7) \\ q_{j-1} = q_j - h \frac{\mathrm{d}q}{\mathrm{d}t} + \frac{h^2}{2} \frac{\mathrm{d}^2 q}{\mathrm{d}t^2} - \frac{h^3}{6} \frac{\mathrm{d}^3 q}{\mathrm{d}t^3} + \frac{h^4}{24} \frac{\mathrm{d}^4 q}{\mathrm{d}t^4} - \frac{h^5}{120} \frac{\mathrm{d}^5 q}{\mathrm{d}t^5} + \frac{h^6}{720} \frac{\mathrm{d}^6 q}{\mathrm{d}t^6} + \mathcal{O}(h^7) . \end{cases}$$

Under these conditions, the left-hand side of equation (9) does not vanish but defines the truncation error $\mathcal{T}_h(q_i)$. The scheme (9) is sixth-order accurate on truncation error:

$$\mathcal{T}_h(q_j) = -\frac{1}{21600} \,\omega^8 \,h^6 \,q_j + \mathcal{O}(h^8) \,.$$

Regarding numerical stability, a condition is obtained from solving a characteristic polynomial of equation (9),

$$\frac{1}{h^2} \left(1 - 2r + r^2 \right) + \frac{\omega^2}{30} \left(1 + 28r + r^2 \right) + \frac{\omega^4 h^2}{1800} \left(1 - 92r + r^2 \right) + \frac{\omega^6 h^4}{1800} r = 0.$$

The corresponding discriminant is

$$\Delta = \frac{\omega^2}{h^2} \left(h^2 \omega^2 - 10 \right) \left(h^2 \omega^2 - 30 \right) \left(h^2 \omega^2 - 60 \right) \left(h^4 \omega^4 - 84h^2 \omega^2 + 720 \right) .$$

The polynomial $(h^4\omega^4 - 84h^2\omega^2 + 720)$ has two real roots in $h^2\omega^2$. Therefore,

(10)
$$\Delta < 0 \quad \text{when} \quad 0 < h \,\omega < \sqrt{42 - 6\sqrt{29}}$$

This restriction supersedes the previous stability condition (7). Under this new restriction, two complex conjugate roots of unit module are obtained, guaranteeing numerical stability. Let us remark that $\sqrt{42-6\sqrt{29}} \approx \pi$. As such, $h < \frac{T}{2}$ when $\omega = \frac{2\pi}{T}$. The method remains stable by using a little more than two points per period of oscillation in this case.

• Symplectic Structure

The generalized momentum is defined on the right by

(11)
$$p_r = \frac{\partial L_r}{\partial q_r} \left(q_\ell, q_r \right)$$

In the case of the harmonic oscillator,

$$p_r = m\frac{q_r - q_\ell}{h} + \frac{m}{6\,\delta} \left[-300\,h\,\omega^2\,\left(q_l + 2\,q_r\right) + 5\,h^3\,\omega^4\,\left(q_l + 8\,q_r\right) - \frac{1}{2}\,h^5\,\omega^6 q_r \right]$$

By noticing that $p_j = \frac{\partial}{\partial q_r} L_r(q_{j-1}, q_j)$, equation (8) gives $p_j = -\frac{\partial}{\partial q_\ell} L_r(q_j, q_{j+1})$, and p_{j+1} is calculated according to (11). A discrete system involving the momentum and the state is obtained:

(12)
$$\begin{cases} \frac{p_{j+1} - p_j}{h} = -m\omega^2 \frac{(h^2\omega^2 - 60)}{12(h^2\omega^2 - 10)} (q_j + q_{j+1}), \\ \frac{q_{j+1} - q_j}{h} = -\frac{12h^2\omega^2 - 30}{(h_j^4\omega^4 - 84h^2\omega^2 + 720)} \left(\frac{p_j + p_{j+1}}{m}\right). \end{cases}$$

The system (12) gives the recurrence iteration scheme

(13)
$$\begin{pmatrix} p_{j+1} \\ q_{j+1} \end{pmatrix} = \Phi \begin{pmatrix} p_j \\ q_j \end{pmatrix}, \quad \Phi = \frac{1}{\widetilde{\delta}} \begin{pmatrix} a & b \\ c & a \end{pmatrix}$$

with

(14)
$$\begin{cases} \widetilde{\delta} = 1 + \frac{h^2 \omega^2}{30} + \frac{h^4 \omega^4}{1800} \\ a = 1 - \frac{7}{15} h^2 \omega^2 + \frac{23}{900} h^4 \omega^4 - \frac{1}{3600} h^6 \omega^6 \\ b = \frac{m h \omega^2}{43200} \left(h^2 \omega^2 - 60 \right) \left(h^4 \omega^4 - 84 h^2 \omega^2 + 720 \right) \\ c = \frac{h}{m} \left(1 - \frac{2}{15} h^2 \omega^2 + \frac{1}{300} h^4 \omega^4 \right). \end{cases}$$

Let us remark that det $\Phi = 1$, so the discrete flow (13) is symplectic (see *e. g.* [9]). The harmonic oscillator preserves the energy quantity $H(p,q) = \frac{1}{2m}p^2 + \frac{m\omega^2}{2}q^2$. According to [2], and using (14) the Lobatto scheme preserves the discrete energy

(15)
$$H_d(p,q) = \frac{c}{2\,\widetilde{\delta}}\,p^2 - \frac{b}{2\,\widetilde{\delta}}\,q^2$$

Under the stability condition (10), we have the inequality -b > 0.

5) Numerical Experiments

The harmonic oscillator evolution was simulated using the Lobatto scheme (13) (14). Results for both N = 3 meshes and N = 10 meshes are displayed on Figure 1, compared with the exact solutions $q(t) = \frac{\pi}{2} \cos(\omega t)$ and $p(t) = -\frac{\pi}{2} m \omega \sin(\omega t)$ on a period T = 1. Comparable results from both the implicit midpoint and Simpson schemes are also provided for reference (see *e. g.* [2]). Quantitative errors with the ℓ^{∞} norm are given in Table 1. An asymptotic order of convergence of 6 is estimated for the momentum, states, and energy. Figure 2 shows the ℓ^{∞} energy error norm evolution across 100000 periods of motion.

Table 1: Errors in the maximum norm. The Lobatto approximation is sixth-order accurate and preserves a discrete energy. Comparable values from both the implicit midpoint and Simpson schemes can be found in [2]. The estimated convergence order is the closest integer α measuring the ratio of successive errors in a given line by a negative power of 2 of the type $2^{-\alpha}$.

Number of meshes	10	20	40	order
Momentum p	8.95×10^{-6}	1.39×10^{-7}	2.17×10^{-9}	6
State q	7.64×10^{-7}	1.19×10^{-8}	1.88×10^{-10}	6
Energy $H(p,q)$	6.62×10^{-5}	1.10×10^{-6}	1.70×10^{-8}	6
Discrete energy $H_d(p,q)$	2.66×10^{-15}	1.33×10^{-15}	2.22×10^{-15}	exact

Figure 1: Harmonic oscillator evolution for the momentum p and state q. Comparison of the Lobatto symplectic scheme against the exact solution for (a) N = 3 meshes, and (b) N = 10 meshes. Lobatto's solutions are very close to the exact ones for as little as 3 meshes per oscillation period. Note that the momentum data have been rescaled.

Figure 2: Over 100000 periods of motion, the ℓ^{∞} energy error growth rate is of: 2.50×10^{-11} when h = 0.1, 5.45×10^{-14} when h = 0.05, and 1.35×10^{-13} when h = 0.025.

5) Conclusion and Perspectives

A symplectic Lobatto integrator has been proposed in this contribution and tested on a harmonic oscillator. The method is symplectic, conditionally stable, and sixth-order accurate for both the state and the momentum. After completing this work, the authors noticed that

FRANÇOIS DUBOIS AND JUAN ANTONIO ROJAS-QUINTERO

the scheme (13) (14) was already published in [7]. Our analysis coincides with that of [7]. Nevertheless, the tables and figures of our contribution present new data.

It has already been observed in [2,3], that the internal degrees of freedom cannot be eliminated a nonlinear case. Newton's algorithm for the numerical solution, as well as special elliptic functions for the exact solution will be required. This analysis, which is absent in [7], is left for future work along with the formulation of the integrator on multi-degrees of freedom nonlinear systems.
