Visual Self-Supervised Learning (SSL) currently underperforms Contrastive Language-Image Pretraining (CLIP) in multimodal settings such as Visual Question Answering (VQA). This multimodal gap is often attributed to the semantics introduced by language supervision, even though visual SSL and CLIP models are often trained on different data. In this work, we ask the question: "Do visual self-supervised approaches lag behind CLIP due to the lack of language supervision, or differences in the training data?" We study this question by training both visual SSL and CLIP models on the same MetaCLIP data, and leveraging VQA as a diverse testbed for vision encoders. In this controlled setup, visual SSL models scale better than CLIP models in terms of data and model capacity, and visual SSL performance does not saturate even after scaling up to 7B parameters. Consequently, we observe visual SSL methods achieve CLIP-level performance on a wide range of VQA and classic vision benchmarks. These findings demonstrate that pure visual SSL can match language-supervised visual pretraining at scale, opening new opportunities for vision-centric representation learning.

Date: April 1, 2025 Project Page: https://davidfan.io/webssl/

1 Introduction

Visual representation learning has evolved along two distinct paths with different training approaches. Language-supervised methods such as Contrastive Language-Image Pretraining (CLIP) (Radford et al., 2021; Zhai et al., 2023) use paired image-text data to learn representations that are enriched with linguistic semantics. Self-Supervised Learning (SSL) methods (Zhang et al., 2016; Chen et al., 2020a; He et al., 2022; LeCun, 2022; Oquab et al., 2023) learn from images alone, without language.

Despite SSL models outperforming languagesupervised models on classic vision tasks such as classification and segmentation (Oquab et al., 2023), they are less commonly adopted in recent multimodal large language models (MLLMs) (Liu et al., 2023a, 2024a; Agrawal et al., 2024; Tong et al., 2024a; Beyer et al., 2024; Li et al., 2024; AI@Meta, 2024). This difference in adoption is partially due to a performance gap in visual question answering (see Figure 1), particularly for OCR & Chart interpretation tasks (Tong et al., 2024a; Shi et al., 2024).

Beyond methodology differences, these approaches

🔿 Meta

Figure 1 We compare the scaling behavior of visual SSL and CLIP on 16 VQA tasks from the Cambrian-1 suite under different data and model size regimes. Prior visual SSL methods achieved strong performance on classic vision tasks, but have underperformed as encoders for multimodal instruction-tuned VQA tasks. Our results show that with appropriate scaling of models and data, visual SSL can match the performance of language-supervised models across all evaluated domains—even OCR & Chart.

have also been separated by data scale and distribution (Figure 1). CLIP models typically train on

Figure 2 Visual SSL 2.0 changes. In this work, we adopt three improvements to the visual SSL pipeline: 1) Training on billion-scale web data, curated through the MetaCLIP pipeline, to move beyond "conventional" datasets; 2) Scaling model architecture from sub-billion parameter models to models exceeding 1 billion parameters; and 3) Incorporating VQA as a complementary evaluation protocol to comprehensively assess visual features. These changes enable us to study visual SSL at a larger scale and observe scaling trends previously unobserved in smaller-scale experiments.

billion-scale image-text pairs from the web (Schuhmann et al., 2022; Chen et al., 2023; Xu et al., 2024b), while SSL methods use million-scale datasets such as ImageNet (Deng et al., 2009) or hundred-million scale data with ImageNet-like distributions (Ridnik et al., 2021; Oquab et al., 2023).

In this work, we investigate a fundamental question: Is language supervision necessary to pretrain visual representations for multimodal modeling? Rather than seeking to replace language-supervised approaches, we aim to understand the intrinsic capabilities and limitations of visual self-supervision at scale for multimodal applications. To conduct a fair comparison, we train SSL models on the same billionscale web data used for state-of-the-art CLIP models specifically the MetaCLIP dataset (Xu et al., 2024b). This approach controls for data distribution differences when comparing visual SSL and CLIP.

For evaluation, we primarily use visual question answering (VQA) as a framework to evaluate SSL models across a diverse set of capabilities at scale. VQA evaluation suites span vision-centric, visual reasoning, and OCR & Chart tasks, and have been shown to be a more diverse testbed for assessing vision encoders (Tschannen et al., 2024; Wan et al., 2024; Fini et al., 2024; Tong et al., 2024a), reflecting the broader perception challenges found in real-world distributions. We adopt the evaluation suite proposed in Cambrian-1 (Tong et al., 2024a), which evaluates performance across 16 tasks spanning 4 distinct categories of VQA: General, Knowledge, OCR & Chart, and Vision-Centric.

We train Web-SSL, a family of visual SSL models ranging from 1 to 7 billion parameters, using the above setting for direct and controlled comparison to CLIP. As a result of our empirical study, we contribute several insights:

- Visual SSL can match and even surpass languagesupervised methods for visual pretraining, on a wide range of VQA tasks—even on languagerelated tasks such as OCR & Chart understanding (Figure 3).
- Visual SSL scales well with respect to model capacity (Figure 3) and data (Figure 4), indicating that SSL has significant untapped potential.
- Visual SSL can maintain competitive traditional vision performance on classification and segmentation, even while improving at VQA (Figure 7).
- Training on a higher ratio of images containing text is especially effective for improving OCR & Chart performance (Question 4). Exploring data composition is a promising direction.

This work serves as a proof of concept that offers a compelling vision-centric alternative to the recent CLIP-dominated trend, and opens new opportunities for future research. We plan to open-source our Web-SSL vision models, and we hope to inspire the broader community to unlock the full potential of visual SSL in the multimodal era.

2 From Visual SSL 1.0 to 2.0

In this section, we describe our experimental setup, which extends previous SSL works by (1) scaling dataset size to billion-scale images (Section 2.1), (2) scaling model size beyond 1B parameters (Section 2.2), and (3) evaluating vision models using open-ended VQA tasks (Section 2.3), in addition to classic vision benchmarks such as ImageNet-1k (Deng et al., 2009) and ADE20k (Zhou et al., 2019).

2.1 Beyond ImageNet Pretraining

To study whether visual SSL can match the performance of CLIP, we start by adopting the same data that drove CLIP's success. We thus leverage the MetaCLIP dataset (Xu et al., 2024b,a), which has enabled the most successful open-source reproduction of CLIP to-date.¹ We use 2 billion samples from MetaCLIP, which we refer to as MC-2B. We train SSL methods on only the images, and CLIP on the image-text pairs.

This controls for data distribution and size as confounding variables, and enables a fairer comparison of the pretraining methods themselves, while ensuring sufficient data diversity and scale.

2.2 Scaling Up Vision Models to Billion Scale

We can also increase model size. Inspired by advancements in scaling language models (Brown et al., 2020; Kaplan et al., 2020; OpenAI, 2022), we train Vision Transformers (ViTs) with 1B, 2B, 3B, 5B, and 7B parameters, on only the images from MC-2B, to study the properties of larger-scale visual SSL models trained on web-scale data. We adapt ViT-g from Oquab et al. (2023) as ViT-1B, and define new configurations for ViT-2B to 7B (Table 1); see Appendix A for model details.

Model	Width	Depth	Heads	MLP
ViT-1B	1536	40	24	6144
ViT-2B	2688	24	21	10752
ViT-3B	3072	26	24	12288
ViT-5B	3584	32	28	14336
ViT-7B	4096	32	32	16384

Table 1 Model architecture details. For consistency, we denote ViT-g from Oquab et al. (2023) as ViT-1B.

2.3 Multimodal LLMs as an Evaluation Protocol

In addition to conventional evaluation protocols, such as ImageNet-1k linear probe, we also evaluate our vision encoders using VQA, a flexible and robust evaluation protocol that reflects the diversity of realworld perceptual challenges (Tschannen et al., 2024; Tong et al., 2024a), as shown in Figure 2.

Here, we study all vision encoders using the same controlled setting to ensure fair comparison. Specifically, we use the same two-stage visual instruction tuning procedure and data as Cambrian-1 (Tong et al., 2024a). First, a lightweight MLP adapter is added to project the vision encoder features into the same dimensionality as the LLM, and only this MLP adapter is trained. In the second stage, both the MLP adapter and LLM are finetuned. To enable controlled comparison, the vision encoder remains frozen in both stages, and all experiments use the same training recipe as well as Llama-3 8B Instruct (Touvron et al., 2023) backbone. We provide detailed training datasets and hyperparameters in Appendix A.

We then report results on the Cambrian-1 (Tong et al., 2024a) evaluation suite, which is comprised of 16 VQA benchmarks spanning four established domains: General, Knowledge, OCR & Chart, and Vision-Centric. The average VQA performance is the average of the four subcategories. Each subcategory has 4 benchmarks and is equally weighted.

3 Scaling Visual SSL

In this section, we explore the scaling behavior of visual SSL models with respect to both model and data size, as a result of training on only images from MC-2B. We focus on DINOv2 (Oquab et al., 2023) as the visual SSL method in this section, and discuss MAE (He et al., 2022) in Section 4.

In Section 3.1, we increase model size from 1B to 7B while keeping the training data fixed at 2 billion MC-2B images—unless otherwise denoted. We use the off-shelf training code and recipe for each method, and do not change the recipe for different model sizes in order to control for confounding variables. In Section 3.2, we shift our focus to scaling total data seen for a fixed model size, and analyze how performance evolves as the number of images seen during training increases from 1 billion to 8 billion.

3.1 Scaling Model

The intention of scaling model size is both to find the ceiling of visual SSL under this new data regime, and to identify any unique behavior that emerges in larger models.

We thus pretrain DINOv2 ViT models, ranging from 1B to 7B parameters, using 2 billion unlabeled images at 224×224 resolution from MC-2B—without high-resolution adaptation (Oquab et al., 2023)—to ensure fair comparison with CLIP. We refer to these models as Web-DINO throughout the paper. For a controlled comparison, we also train CLIP models of the same sizes on the same data.

¹The data used to train the original CLIP is closed-source.

Figure 3 Scaling behavior of Web-DINO and CLIP ViTs trained on MC-2B. The x-axis shows model sizes from 1B to 7B parameters on a log scale. We observe novel "scaling behavior" with Web-DINO models across all categories, with particularly pronounced improvements in the OCR & Chart and Vision-Centric domains as model size increases. In contrast, CLIP models demonstrate limited scaling benefits, with performance saturating at moderate model sizes. The two model families exhibit complementary strengths: CLIP models excel at OCR & Chart VQA, and Web-DINO models are superior at Vision-Centric VQA, while remaining competitive in all other categories.

We evaluate each model with VQA and present the results in Figure 3. We will first discuss the overall performance trend and then turn to specific category performance. To the best of our knowledge, this is the first instance of a vision encoder trained purely with visual self-supervision achieving performance parity with language-supervised encoders on VQA—even in the OCR & Chart category, which is traditionally considered to be highly text-dependent.

Performance trend. We compare the performance trend as model capacity increases in Figure 3. Web-DINO's Average, OCR & Chart, and Vision-Centric VQA performance improves nearly log-linearly with increasing model size, while General and Knowledge improve to a smaller degree. In contrast, CLIP's performance in all VQA categories largely saturates after 3B parameters. This suggests that while smaller CLIP models may be more data-efficient, this advantage largely dissipates for larger CLIP models. The continual improvement from increasing Web-DINO model capacity also suggests that visual SSL benefits from larger model capacity, and that scaling visual SSL past 7B parameters is a promising direction.

Category-specific performance. In terms of categoryspecific performance, DINO also increasingly outperforms CLIP on Vision-Centric VQA and largely closes the gap with CLIP on OCR & Chart and Average VQA (Figure 3), as model size increases. At 5B parameters and above, DINO can exceed the Average VQA performance of CLIP, despite being trained solely on images and without language supervision. These results suggest that vision-only models, when trained on CLIP-distribution images, can develop strong visual features that are comparable to those of language-supervised vision encoders.

3.2 Scaling Examples Seen

Previously, we focused on single-epoch training, where each of the 2B unique images in MC-2B is seen only once. Here, we investigate the impact of increasing the number of examples seen by training Web-DINO ViT-7B on data ranging from 1 billion to 8 billion images from MC-2B.

As shown in Figure 4, General and Knowledge VQA performance improves incrementally with more examples seen, saturating at 4B and 2B examples respectively. Vision-Centric VQA performance improves sharply from 1B to 2B examples, and saturates beyond 2B examples. In contrast, OCR & Chart is the only category that shows consistent improvement with more examples seen. This suggests that as the model sees more data, it learns a representation that is increasingly well-suited for text-related tasks, yet without marked degradation on other capabilities.

Furthermore, when compared to a CLIP model of the same size (ViT-7B), Web-DINO consistently outperforms CLIP on average VQA performance given the same number of samples seen (Figure 4). Notably, after seeing 8B samples, Web-DINO closes the performance gap with the CLIP model on OCR & Chart VQA tasks. This provides further evidence suggesting that visual SSL models have the potential to scale better than language-supervised models.

Collectively, the results in Figure 3 and 4 indicate that as model size and examples seen increase, visual SSL learns features that are increasingly effective for VQA in general, but especially on OCR & Chart. Our results suggest that CLIP-based models do not hold an absolute advantage compared to visual SSL. In Section 4, we delve deeper into the underlying mechanisms driving this trend.

Figure 4 Scaling up examples seen when training Web-DINO-7B. Performance across different VQA categories as training data increases from 1B to 8B images. While General and Vision-Centric tasks show diminishing returns after 2B images, OCR & Chart tasks demonstrate continued improvement, contributing to steady gains in average performance. Further, Web-DINO consistently outperforms same-size (ViT-7B) CLIP models with different training samples seen. The x-axis plots training data size on a log-scale.

4 Scaling Analysis and Findings

In Section 3, we demonstrated that visual SSL models scale well with model size and training set size. These observations raise further questions about the generality and implications of these phenomena. To deepen our understanding, we investigate five key aspects, including whether scaling behavior extends to other vision-only models (Question 1), if SSL models also exhibit scaling behavior on smaller and more conventional data (Question 2), and whether SSL can retain competitive performance on classic vision tasks (Question 3). Additionally, we explore why scaling particularly enhances OCR & Chart performance (Question 4), and highlight emergent properties that arise via scaling visual SSL (Question 5). In this section, we provide a detailed analysis of these findings.

Question 1

Does the observed scaling behavior generalize to other visual SSL methods?

In previous sections, we derived our findings from DINOv2, a joint embedding visual SSL method. Here, we extend our analysis to a masked modelling based visual SSL method—Masked Autoencoder (MAE) (He et al., 2022). We train MAE on MC-2B (denoted as Web-MAE) using ViT models ranging from 1B to 5B parameters and compare the results with Web-DINO models in Figure 5.

Web-MAE models exhibit similar scaling behavior to Web-DINO models, with average VQA performance improving consistently as model size increases. Compared to joint embedding methods, Web-MAE models learn features that are particularly well-suited for OCR & Chart tasks but underperform in other domains. These results suggest that the "scaling behavior" observed in VQA tasks generalizes across different visual SSL methods. We also note that different visual SSL approaches learn distinct representations even when trained under the same conditions, as demonstrated by Web-MAE's OCR performance.

Question 2

Does visual SSL exhibit similar scaling behavior on smaller scale conventional data, such as ImageNet?

We pretrain Web-DINO 1B, 2B, and 3B models for 300 epochs on ImageNet-1k, a conventional pretraining dataset for SSL, following the recipe from (Oquab et al., 2023). We compare these variants to those trained on MC-2B. We evaluate their downstream VQA performance and ImageNet-1k linear probing results. As shown in Figure 6, models pretrained on ImageNet-1k exhibit consistently inferior performance across all the metrics. Moreover, unlike models trained on MC-2B, those trained on ImageNet-1k do not improve with increasing model sizes. This highlights the importance of training visual SSL on more diverse and larger datasets. This echoes recent findings that increasing dataset sizes and diversity drive LLM scaling (Kaplan et al., 2020; Hoffmann et al., 2023; Chowdhery et al., 2022), and also that pretraining data distribution is critical to downstream performance (Liu and He, 2025).

Question 3

How do scaled models perform on classic vision tasks?

We evaluate Web-DINO models, ranging from 1B

Figure 5 Web-MAE trained on MC-2B. Web-MAE also exhibits consistent scaling behavior as model size increases. Notably, Web-MAE demonstrates better performance in OCR & Chart tasks, achieving higher accuracy than Web-DINO across all model sizes.

Figure 6 Comparison of ImageNet-1k and MC-2B Pretraining. Increasing the diversity and scale of pretraining data improves model performance on VQA accuracy and ImageNet linear probing. Unlike MC-2B pretraining, training on ImageNet does not exhibit a clear scaling trend.

to 7B parameters, on classic vision benchmarks including linear probing on ImageNet-1k (Deng et al., 2009), semantic segmentation on ADE20K (Zhou et al., 2019), and depth estimation on NYUv2 (Silberman et al., 2012). Following the evaluation protocol of DINOv2 (Oquab et al., 2023), we freeze the vision encoder; see Appendix A for details. As shown in Figure 7, Web-DINO's performance improves modestly with increasing model size. Web-DINO achieves strong performance across all benchmarks, outperforming MetaCLIP by a significant margin and remaining competitive with off-shelf DINOv2, even outperforming it on ADE20K +ms. Note that the comparison with off-shelf DINOv2 is not exactly apples-to-apples, as we do not use high-resolution adaptation (Oquab et al., 2023), in order to maintain the same input resolution as CLIP. Additionally, the DINOv2 training data has a higher correlation with these classic vision benchmarks, detailed further in Appendix E. These differences suggest that there remains considerable room for further improvement in our model's classic vision performance.

However, we observe that the scaling behavior in classic vision tasks is less pronounced compared to VQA. This finding, along with insights from previous work (Tong et al., 2024a; Fini et al., 2024; Naeem et al., 2024), reinforces the value of VQA as a comprehensive vision model evaluation framework. While

classic benchmarks remain important, VQA provides a complementary view into model performance via offering a diverse set of tasks that are grounded in real-world perceptual challenges.

Question 4

Why does web-scale data improve OCR & Chart performance?

In Section 3, we observed that increasing model size and examples seen leads to unprecedented improvements in OCR & Chart performance for visual SSL models. This is surprising since current off-the-shelf visual SSL methods are notably poor at OCR & Chart understanding compared to language-supervised models (Tong et al., 2024a; Shi et al., 2024).

One possible explanation is that web-scale image datasets already contain a degree of textual information. Unlike object-centric datasets such as ImageNet, images from the web often contain text (e.g. labels, signs, diagrams, etc.). Larger capacity and more data might aid visual SSL models to extract and leverage this textual information.

To test this hypothesis, we apply an off-the-shelf MLLM—SmolVLM2 (Allal et al., 2025)—to identify images containing text. See Figure 8 for qualitative examples and Appendix A for details. This results in

Figure 7 Performance of Web-DINO models on classic vision tasks. All models achieve strong performance across ImageNet-1k classification, ADE20K segmentation, and NYU Depth estimation, and all tasks experience moderate improvements from increasing model size from 1B to 7B parameters. Web-DINO outperforms MetaCLIP (HF) and is competitive with DINOv2 (HF). (HF) denotes the largest official Hugging Face released version.

			V	QA Evaluat	or		Break	down of OC	R & Chart	Tasks
	% of				Vision	OCR				
Method	MC-2B	AVG	General	Knowledge	Centric	Chart	ChartQA	OCRBench	TextVQA	DocVQA
CLIP 2B	100%	53.0	72.2	48.8	55.0	36.1	32.8	32.9	52.6	26.0
Web-DINO 2B	100%	50.8	72.8	47.1	56.4	26.8	23.3	15.6	49.2	19.0
Web-DINO $2B$	50.3%	53.4 (+2.6)	73.0 (+0.2)	51.7 (+4.6)	55.6 (-0.8)	33.2 (+6.4)	31.4 (+8.1)	27.3 (+11.7)	51.3 (+2.1)	23.0 (+4.0)
Web-DINO $2B$	1.3%	53.7 (+2.9)	70.7 (-2.1)	47.3 (+0.2)	56.2 (-0.2)	40.4 (+13.6)	47.5 (+24.2)	29.4 (+13.8)	52.8 (+3.6)	32.0 (+13.0)

Table 2 Impact of data filtering on SSL model performance. We compare Web-DINO ViT-2B models trained on MC-2B with different levels of text filtering (full, 50.3%, and 1.3%) against CLIP ViT-2B trained on full MC-2B. OCR & Chart performance improves with progressively aggressive filtering, with the 1.3% filter achieving the best results. Despite receiving zero language supervision, SSL models can surpass CLIP in text-centric tasks while maintaining strong overall performance.

Figure 8 Examples of filtered MC-2B images. The Light filter (*Middle*) identifies images containing text, retaining 50.3% of the images. The Heavy filter (*Right*) identifies images explicitly containing charts and documents, retaining only 1.3% of MC-2B.

two curated datasets: (i) Light filter: retains 50.3% of Web-DINO and contains images with any textual content. (ii) Heavy filter: retains 1.3% of MC-2B and contains images with charts, tables, or documents.

We train Web-DINO ViT-2B models on these filtered datasets, with each experiment using 2 billion seen examples (meaning filtered datasets undergo multiple epochs). As shown in Table 2, the model trained on lightly filtered data outperforms the full data variant by +6.4% on OCR & Chart, while maintaining strong performance in other categories. The model trained on heavily filtered data performs better and

outperforms even the language-supervised CLIP ViT-2B trained on full data by +4.3% on OCR & Chart. Likewise, heavy filtering also improves Average VQA performance, outperforming the full data Web-DINO ViT-2B by +2.6% and even the full data CLIP ViT-2B by +0.7%. This means that is it possible for visual SSL models to outperform CLIP models of the same size, with only a fraction of the total data (in this case 1.3% of MC-2B).

The improvement in OCR & Chart from training on heavily filtered data is particularly pronounced for ChartQA (+24.2%), OCRBench (+13.8%), and DocVQA (+13.0%), while performance remains competitive in all other categories. These results demonstrate that self-supervised visual models, when trained on images containing more text in them, can develop high-quality text understanding capabilities without language supervision. It suggests that data composition—rather than purely scale or language supervision—is crucial for developing strong OCR & Chart understanding abilities.

Although it is not surprising that skewing the data in favor of OCR & Chart would improve OCR & Chart capabilities, it is surprising that simple data filtering can outperform language supervision on the full data. This simple proof of concept suggests that similar

Figure 9 Alignment score between Web-DINO and LLMs. Moving from DINOv2 to Web-DINO improves the alignment between the image and the corresponding text representations obtained by LLMs. Increasing model size from 1B to 7B parameters shows gradual improvement, while training on larger data quantities (4B/8B samples) yields the most significant alignment gains.

techniques may be used to help visual SSL bridge future gaps in other capabilities.

Question 5

Why can SSL learn strong visual representations for multimodal modeling, without language supervision?

Thus far, we have seen that visual SSL models can not only become competitive with CLIP models, but also that they can excel at tasks previously thought to require language. This raises an important question: why do vision-only models learn features that work well for multimodal models, even in the absence of language supervision?

We hypothesize that SSL models learn features increasingly aligned with language as model size and examples seen increases. Following Huh et al. (2024), we evaluate intrinsic representational alignment by computing a matching metric between the vision encoder and language model, using image-text pairs from the Wikipedia Captions dataset (Srinivasan et al., 2021). We use off-the-shelf DINOv2 (Oquab et al., 2023) and Web-DINO as vision encoders, and off-the-shelf Llama-3.1 8B and 70B (Touvron et al., 2023) as the language models, *without* any visual instruction tuning nor alignment procedure.

As shown in Figure 9, we observe three key trends: (1) training on more diverse data (MC-2B) improves alignment with LLMs (DINOv2 ViT-1B \rightarrow Web-DINO ViT-1B); (2) increasing the vision model size leads to slightly higher alignment (Web-DINO ViT-

 $1B \rightarrow ViT-7B$); and (3) seeing more training samples further enhances alignment (Web-DINO ViT-7B trained on 2B samples $\rightarrow 8B$ samples).

These findings suggest that as model size and, in particular, training samples scale, vision models naturally develop text-sensitive features and achieve strong alignment with LLMs and multimodal tasks, without explicit language supervision.

5 The Web-SSL Model Family

Next, we analyze the overall best performing vision encoders using both VQA and classic vision benchmarks. In Table 3, we show the best results of our vision encoders against recent off-the-shelf vision encoders, in terms of VQA and classic vision tasks.

For VQA, all vision encoders—including off-the-shelf models—are evaluated using the same visual instruction tuning setup detailed in Section 2.3, and mainly 224×224 input resolution for the purpose of fair comparison. Because the goal is not to produce a state-ofthe-art MLLM, we did not employ techniques such as unfreezing the vision encoder, resolution tiling (Liu et al., 2024b), and spatial visual aggregator (Tong et al., 2024a).

For classic vision, we follow the evaluation procedure from Oquab et al. (2023) and evaluate linear probe performance on ImageNet-1k (Deng et al., 2009), ADE20K (Zhou et al., 2019), and NYU Depth v2 (Silberman et al., 2012). The input resolution differs between classic vision tasks, but each model tested uses the same exact settings from Oquab et al. (2023). We emphasize that the primary motivation is still to provide controlled insights.

Performance at 224px. Web-DINO can outperform off-the-shelf MetaCLIP in both VQA and classic vision tasks. Web-DINO is even able to match the performance of SigLIP and SigLIP2 on VQA despite seeing $5 \times$ less data and receiving no language supervision. In general, Web-DINO outperforms all off-shelf language-supervised CLIP models at traditional vision benchmarks. Although our best Web-DINO model is 7B parameters, the results from Section 3.1 and Section 3.2 suggest that CLIP models saturate beyond moderate model and data sizes, while visual SSL improves progressively with increasing model and data size. Web-DINO also outperforms off-theshelf visual SSL methods, including DINOv2 (Oquab et al., 2023), in all VQA categories. Web-DINO is also competitive in traditional vision benchmarks.

Performance beyond 224px. Next, we discuss the performance of higher resolution models. Following

Table 3 Comparison with other vision models. Web-DINO ViT-7B achieves competitive performance with CLIP models on VQA without language supervision and surpasses them on traditional vision tasks. Compared to other self-supervised models like DINOv2, Web-DINO significantly narrows the performance gap with CLIP on VQA tasks, particularly excelling in OCR & Chart understanding. These results demonstrate that SSL can effectively produce strong visual representations for both multimodal and classic vision tasks.

Oquab et al. (2023), we additionally fine-tune Web-DINO for 20k steps. We do this for resolutions of 378 and 518, to compare against the higher-resolution off-shelf versions of SigLIP as well as DINO. See Appendix C for training details. From 224 to 378 to 518 resolution, Web-DINO improves steadily at average VQA, with notable gains in OCR & Chart performance. Classic vision performance improves modestly with higher resolution. At 384 resolution, Web-DINO trails behind SigLIP. At 518 resolution, Web-DINO is largely able to bridge the gap. The results suggest that Web-DINO may benefit from further increasing high-resolution adaptation.

6 Related Work

Visual self-supervised learning methods. Early visual SSL methods explored various pretext tasks for pretraining (Wang and Gupta, 2015; Doersch et al., 2015; Noroozi and Favaro, 2016; Zhang et al., 2016; Gidaris et al., 2018; Balestriero et al., 2023). More recently, research has converged on two primary approaches: joint embedding methods and masked image modeling. Joint embedding methods learn invariant features by aligning representations of different augmented views (He et al., 2019; Misra and Van Der Maaten, 2019; Chen et al., 2020a; Grill et al., 2020; Chen et al., 2020b; Chen and He, 2021; Chen et al., 2021; Caron et al., 2021; LeCun, 2022; Chen et al., 2022; Garrido et al., 2023), while masked modeling (Zhou et al., 2021; He et al., 2022; Wei et al., 2022; Fan et al., 2023; Assran et al., 2023; Woo et al., 2023; Bar et al., 2024; Bai et al., 2024; Carreira et al., 2024) learns by predicting masked visual inputs.

Our work complements SSL research focused on pretraining algorithms, by taking off-the-shelf training code and training visual SSL at scale with a controlled experimental setup. In Question 1, we show that the observed scaling behavior generalizes across both joint embedding and masked modeling SSL methods, and is likely not a method-specific phenomena.

Data used to train vision models. Both supervised (He et al., 2016; Xie et al., 2016; Dosovitskiy et al., 2021; Liu et al., 2022) and SSL vision models have traditionally relied on standard datasets such as MNIST (LeCun, 1998), CIFAR-10 (Krizhevsky et al., 2009), and ImageNet (Deng et al., 2009; Ridnik et al., 2021). More recently, self-supervised methods have scaled to larger unlabeled datasets, such as YFCC (Thomee et al., 2016), LVD-142M (Oquab et al., 2023), and IG-3B (Singh et al., 2023); however, these methods still exhibit a significant performance gap compared to language-supervised models on VQA.

In contrast, language-supervised models (Radford

et al., 2021; Zhai et al., 2023; Sun et al., 2023, 2024; Xu et al., 2024b; Tang et al., 2025) leverage significantly larger image-text datasets, from WIT-400M (Radford et al., 2021) to billion-scale web data (Schuhmann et al., 2022; Fang et al., 2024; Xu et al., 2024b; Gadre et al., 2022), with some using up to 100B image-text pairs (Wang et al., 2025). Studies suggest that pretraining data distribution is more critical for downstream performance than specific training methodologies (Fang et al., 2022; Liu and He, 2025).

Our work bridges these paradigms by pretraining SSL models on web-scale data. Through controlled experiments (Section 3 and 4), we show that (1) visual SSL models are sensitive to the training distribution, (2) increasing data diversity and quantity significantly improves performance on a diverse range of VQA tasks, and (3) training on a higher concentration of images containing text is highly effective for improving OCR & Chart understanding.

Evaluating vision models. Classic works have primarily used image classification (LeCun, 1998; Krizhevsky et al., 2009; Deng et al., 2009; Bossard et al., 2014; Hendrycks et al., 2019, 2020) to evaluate learned representations. More recent SSL research has expanded evaluation to include image segmentation (Everingham et al., 2010; Cordts et al., 2016; He et al., 2017; Zhou et al., 2019), depth estimation (Silberman et al., 2012; Geiger et al., 2013; Song et al., 2015), and video classification (Soomro et al., 2012; Goyal et al., 2017a; Baruch et al., 2021). Languagesupervised models (Radford et al., 2021; Zhai et al., 2023), due to their two-tower encoder structure, commonly use zero-shot image classification to assess the quality of learned image and text features.

Our work follows recent proposals (Naeem et al., 2024; Fini et al., 2024; Tong et al., 2024a) to evaluate vision encoders on a broader range of VQA tasks (Goyal et al., 2017b; Yue et al., 2024a; Liu et al., 2024c; Fu et al., 2023; Tao and Xie, 2024; Yue et al., 2024b; xAI, 2024) using MLLMs. These VQA tasks complement traditional vision benchmarks by assessing visual features on a more diverse range of real-world perceptual challenges. As shown in Section 3 and Section 4, we find that visual SSL trained on web-scale data learns representations that continue to improve on VQA benchmarks, and—to a lesser degree—also on traditional vision benchmarks.

7 Limitations

In this work, we focus on training visual SSL models without using language. The main limitation of vision-only models, compared to language-supervised models, is that they do not support zero-shot image classification out of the box. However, by integrating visual SSL models into MLLM frameworks through instruction tuning, we show they can achieve impressive downstream performance across classification and other tasks. Another way to achieve zero-shot image classification is to use LiT-style adaptation (Zhai et al., 2022; Jose et al., 2024), but this is outof-scope for our work as we do not use language supervision. To focus on comparing the vision encoder, we fixed the base LLM for visual instruction tuning to Llama-3 8B Instruct (AI@Meta, 2024). We hypothesize that the findings using other LLM backbones would be similar, however this is not in scope for our work. Additionally, while we demonstrate that visual SSL scales well on MetaCLIP data, we leave the exploration of even larger and/or uncurated datasets to future work.

8 Discussion

We show that large-scale visual encoders that are trained with self-supervised language-free objectives can produce high quality visual features for multimodal models. Our results echo the "bitter lesson" (Sutton, 2019) and suggest that imposing less supervision—including language—remains a promising direction for advancing the field of computer vision. We hope our work will inspire further exploration of vision-only approaches, which will enable the construction of next generation vision models that excel at both traditional vision and modern multimodal capabilities.

9 Acknowledgements

We thank Ellis Brown, John Nguyen, Junlin Han, Shengyi Qian, Tyler Zhu, Yuexiang Zhai, Druv Pai, Shusheng Yang, Jihan Yang, Muzi Tao, Boyang Zheng, and Anjali Gupta for reviewing this manuscript. We thank Hu Xu and the MetaCLIP paper authors for creating the MetaCLIP dataset. We thank Mido Assran, Mikael Henaff, Daniel Bolya, Hu Xu, Mark Ibrahim, Russ Howes, and Matthew Muckley for their insightful feedback. We thank Michaël Ramamonjisoa and Marc Szafraniec for their help with image segmentation and depth estimation evaluations. Lastly, we thank Ananya Saxena, Cody Olsen, Mack Ward, Maxwell Taylor, Kalvan Saladi, Dev Satpathy, Dinesh Kannappan, Xiaodong Ma, Jacob Kahn, Gabriel Synnaeve, and Shubho Sengupta for infrastructure support.

A Implementation Details

Training. For training Web-DINO, Web-MAE, and CLIP models, we closely follow the existing opensource codebases: the official DINOv2 and MAE repositories, and the MetaCLIP codebase which builds on top of the OpenCLIP codebase (Cherti et al., 2023). We use Fully Sharded Data Parallel (FSDP) (Zhao et al., 2023) for distributed training of larger models.

For Web-DINO and CLIP pretraining, we follow the exact recipe and hyperparameters from the original paper for their largest model. For MAE pretraining, we observe that training becomes more prone to divergence as model size increases. To mitigate this, we reduce the learning rate from 2.4e-3 to 1.6e-3 and extend the warmup period to 80K iterations. Table 4 provides a summary of the pretraining hyperparameters.

Model	Batch Size	Learning Rate	Warmup
Web-DINO	$3072 \\ 4096 \\ 32768$	3.5e-4	100K
Web-MAE		1.6e-3	80K
CLIP		4e-4	2K

Table 4 Hyperparameters for Web-DINO, Web-MAE and CLIP.

VQA evaluation. For VQA evaluation, we follow Tong et al. (2024a,b) and use Cambrian-Alignment data for MLP projector training and Cambrian-7M for MLP and LLM fine-tuning. We finetune on top of Llama-3 8B Instruct (AI@Meta, 2024). The vision encoder is frozen throughout finetuning. We excluded LAION (Schuhmann et al., 2022) images from the Cambrian data to comply with safety standards. We first encode the images at the model's original input resolution using the pretrained vision encoder. Next, we extract features from the final encoder layer. Following prior approaches (Tong et al., 2024a,b), we then resize the resulting token sequence to a fixed length of 576 tokens through bilinear interpolation. This ensures consistency across evaluations despite variations in input image resolutions. We report configurations in Table 5.

Classic vision evaluation. We follow the evaluation procedure in DINOv2 (Oquab et al., 2023) for all classic vision evaluation: linear probe on ImageNet1k (Deng et al., 2009), ADE20K (Zhou et al., 2019), and NYU Depth v2 (Silberman et al., 2012). For ImageNet-1k, we evaluate models with their pretrained image resolution; For ADE20K and NYU Depth v2, we use the settings from Oquab et al. (2023). For ADE20K, we follow DINOv2 and report the linear and +ms setting. For NYU Depth v2, we report lin. 1 and lin. 4. See the original paper for additional details.

Model architectures. In Table 1, we defined the ViT architectures used in our study. To recap, we first borrowed the ViT-g architecture from Oquab et al. (2023) and named it ViT-1B for consistent notation. We then define 2B, 3B, 5B, and 7B architectures inspired by language model scaling. Specifically, the 2 - 7B architectures are wider than the 1B variant, inspired by language model recipes. Our 7B architecture is almost identical to the Llama-2 7B design, except for the patch embedding layer which is unique to ViTs.

Text filtering. In Question 4, we introduced the "Light" and "Heavy" filters which retain 50.3% and 1.3% of MC-2B respectively. Specifically, we use a small MLLM, SmolVLM2 (Allal et al., 2025), to identify images containing text, using prompts such as "Does this image contain any readable text?". The intention is not to achieve perfect filtering, but rather to skew the data distribution in the general desired direction. See Figure 8 for a visualization of the filtering process and some examples. This results in two curated datasets:

(i) Light filter: Retains 50.3% of the original data, primarily consisting of images with some textual content. Prompt used: "Does this image contain any readable text? Answer only yes or no."

(ii) Heavy filter: Retains only 1.3% of the data, focusing mainly on charts and documents. Prompt used: "Please think carefully before answering. Does this image contain charts, tables, or documents with readable text? Answer only yes or no."

B Full Results

We include full results of all experiments presented in Section 3 and Section 4.

B.1 Web-DINO

Scaling up model sizes. We show quantitative results of scaling up the model under VQA evaluation in Table 6 and classic vision evaluation in Table 7. These are the numerical results for Section 3.1.

Scaling up data sizes. We show quantitative results of scaling up the number of data seen with Web-DINO ViT-7B on VQA evaluation in Table 8 and

Table 6 VQA Evaluation: Web-DINO trained on MC-2B with 2 billion images seen.

classic vision evaluation in Table 9. These are the numerical results for Section 3.2.

Scaling down training data. We show VQA evaluation results from training Web-DINO on less diverse data–ImageNet-1k, in Table 10. These are the full results for scaling down training data experiments in Question 2.

B.2 Web-MAE

We show VQA evaluation results from scaling up MAE trained on MC-2B, in Table 11. These are the full results for Question 1.

B.3 Scaled CLIP Models

We show VQA evaluation results from scaling up MetaCLIP (Xu et al., 2024b) trained on MC-2B, in Table 12. These are the full results for Section 3.1. In contrast to visual SSL methods in Table 7 and Table 11, CLIP models do not exhibit clear scaling behavior.

B.4 Text Filtered Models

We provide full results for Question 4. As shown in Table 13, SSL models learn features particularly well-suited for OCR & Chart tasks when trained on datasets with a higher concentration of text-rich images. This suggests that visual SSL is sensitive to the underlying training distribution and can be effectively steered toward specific downstream applications, such as OCR & Chart.

B.5 Baseline Models

In Table 14, we provide full VQA results for the reference off-shelf models that we evaluated in Section 5.

C High Resolution Adaption of Web-SSL

Following Oquab et al. (2023), we further fine-tune our model under higher resolution settings of 378×378 and 518×518 for 20k iterations. We use a batch size of 2048 and a correspondingly lower learning rate of 1.41e-5. All other parameters remain exactly the same as previously specified, including the learning rate warmup ratio, given the total of 10k iterations.

We also provided detailed benchmark results of high-resolution adaptation of Web-DINO in Table 15.

D Evaluation

Table 16 lists evaluation benchmarks used and their purposes.

E Pretraining Dataset Cards

For reference, in Table 17 we include the data composition of LVD-142M, which was used to train the off-shelf DINOv2 model (Oquab et al., 2023). LVD-142M is a carefully curated data mix closely aligned with downstream classic vision evaluation tasks. In comparison, we leverage MetaCLIP data, which is less curated and collected from 15 snapshots of CommonCrawl (CC).

Table 17 LVD-142M Data Sources. In contrast to LVD-142M, which relies on highly curated data sources drawn from distributions closely aligned with various downstream evaluation tasks (see the table above from Oquab et al. (2023)), our data curation approach adopts the methodology from MetaCLIP (Xu et al., 2024b), utilizing web data collected from 15 snapshots of CommonCrawl (CC) spanning January 2021 through January 2023.
