

Enhancing Traffic Sign Recognition On The Performance Based On Yolov8

Baba Ibrahim, Zhou Kui

Intelligent Vehicle

Institute Of Automotive Engineers, Hubei University of Automotive Technology

Abstract: This paper Traffic sign recognition plays a crucial role in the development of autonomous vehicles and advanced driver-assistance systems (ADAS). Despite significant advances in deep learning and object detection, accurately detecting and classifying traffic signs remains challenging due to their small sizes, variable environmental conditions, occlusion, and class imbalance. This thesis presents an enhanced YOLOv8-based detection system that integrates advanced data augmentation techniques, novel architectural enhancements including Coordinate Attention (CA), Bidirectional Feature Pyramid Network (BiFPN), and dynamic modules such as ODConv and LSKA, along with refined loss functions (EIoU and WIoU combined with Focal Loss). Extensive experiments conducted on datasets including GTSRB, TT100K, and GTSDB demonstrate marked improvements in detection accuracy, robustness under adverse conditions, and real-time inference on edge devices. The findings contribute actionable insights for deploying reliable traffic sign recognition systems in real-world autonomous driving scenarios.

Key words: *Traffic Sign Recognition (TSR), YOLOv8, Coordinate Attention (CA), Bidirectional Feature Pyramid Network (BiFPN), Omni-Directional Dynamic Convolution (ODConv), Large Separable Kernel Attention (LSKA), Enhanced IoU (EIoU), Wise IoU(WIoU), Focal Loss, Real-Time Detection, Autonomous Vehicle, Advance Driver-Assistance Systems(ADAS).*

CHAPTER 1: INTRODUCTION

1.1 Introduction

Traffic Sign Recognition (TSR) is a vital technology for contemporary intelligent transportation systems, particularly for Advanced Driver-Assistance Systems (ADAS) and autonomous cars. It is imperative that vehicles detect and recognize traffic signs accurately in order to ensure road safety and optimal traffic control. Even with incredible advancements in deep learning and computer vision achieved in the last ten years, TSR systems continue to struggle with a plethora of issues in real-world scenarios. Adverse weather, occlusion, and lighting variation can have a profound impact on the recognition performance of even the most high-circuit algorithms. In addition, most of the current state-of-the-art models are computationally costly, and hence real-time processing on embedded or edge hardware is difficult. Considering these limitations, this work proposes the use of YOLOv8—a recent state-of-the-art, single-shot object detector—to enhance TSR performance. Innovative techniques such as anchor-free detection and Mosaic data augmentation are used to develop YOLOv8 that is made to provide high accuracy along with inference speeds. The core aim of this research is to make a robust TSR system that can function reliably under hostile environments without compromising real-time processing. This work will contrast YOLOv8 with traditional methods and other deep learning structures on a variety of datasets, providing insight capable of leading to safer and more effective transport systems [1,2,3].

1.2 Problem Statement

Modern TSR systems have a problem achieving high recognition accuracy in real life because of the weather conditions, occlusion, and lighting levels. Routine techniques relying on deep learning are low performing and under resourced while many deep learning approaches are not much better as they require a lot of power which cannot be optimally allocated to anything but standard edge devices [4],[5]. Further, the generalization of these models is often weak; for example, those created using the German Traffic Sign Recognition Benchmark (GTSRB) [6] do not function effectively in uncontrolled settings. For this reason, a TSR system is needed that is flexible to the changes in an environment and can be deployed in real-life situations without relying on high resource availability.

1.3 Purpose of the Study

This study aims to develop and evaluate a robust TSR system using YOLOv8. The system is intended to achieve:

- Obtain high target recognition accuracy (>99% on benchmark datasets) even in the most difficult environments.
- To be ADAS-compliant and perform processing in real time (more than 80 frames per second).
- Possess improved transfer learning capabilities for disparate datasets such as GTSRB, BelgiumTSC, and DITS.
- A comprehensive evaluation against traditional machine learning and modern deep learning techniques used.

1.4 Research Objectives

The primary objectives of this research are to:

1. Design a TSR system that uses YOLOv8 as a backbone and supports anchor-free detection and Mosaic augmentation.
2. Assess the precision, speed, and robustness of the YOLOv8 backbone model on standard benchmark datasets.
3. Determine the accuracy of YOLOv8 based classifiers (HOG+SVM, LBP+Random Forest) compared to deep learning (AlexNet, ResNet) classifiers.
4. Examine the model's performance in adverse conditions (fog, rain, occlusion) and provide solutions for further improvements.

1.5 Research Questions

This study is guided by the following research questions:

- In terms of accuracy and inference speed, how does the performance of YOLOv8 compare with that of a conventional TSR approach?
- Is it possible for the proposed model to perform well in an adverse environment?

- In the case of TSR implementation, what is the balance between model complexity and real-time processing efficiency?
- How well does the model cross different datasets, and how can its robustness be improved?

1.6 Significance of the Study

This research covers the design and assessment of a TSR system on YOLOv8. The assessment is done on well-known datasets (GTSRB, BelgiumTSC, DITS) with testings in different settings. The study prioritizes real-time efficiency and reliability, but it does not consider all possible scenarios (e.g., very low-light situations). In addition, the platform-dependent nature of the computed benchmarks need to be noted. The findings, however, may be impacted by the hardware configurations being used. Regardless of these constraints, it is hoped that the results will be beneficial for future studies and practical work in the area of TSR.

1.7 Scope and Limitations of the Study

This study focuses on the development and evaluation of a TSR system using YOLOv8. The evaluation is conducted on established datasets (GTSRB, BelgiumTSC, DITS) with testing under various environmental conditions. While the study emphasizes real-time performance and robustness, it does not address every possible real-world scenario (e.g., extreme nighttime conditions). Moreover, the computational benchmarks are platform-dependent; results may vary on different hardware configurations. Despite these limitations, the findings are expected to provide a solid foundation for further research and practical implementations in TSR.

CHAPTER 2: LITERATURE REVIEW

In the context of modern technological advancement, it is important to conduct comprehensive literature analysis to gain better insight into evolution of Traffic Sign Recognition (TSR) systems and possible strategies that are used in handling their complexities. This chapter of the thesis works to provide a detailed history of TSR, its various classifiers, related works on single-frame TSR techniques, whose comparisons focus on the efficiency of each approach.

2.1 Background on Traffic Sign Recognition

The methods of recognizing and interpreting traffic signs have transformed significantly from basic image processing methods to complex deep learning techniques. The first TSR systems

used to use features like hand-crafted processes, color histograms, edge detection, and even texture descriptors for the classification and recognition of traffic signs [7], [8]. Unlike the rest of the world, early benchmarks like the German Traffic Sign Recognition Benchmark (GTSRB) sparked research activity and gave Set benchmarks for algorithms where a dataset was easily accessible and objective comparisons were possible [6]. However, traditional techniques faced serious problems with robustness due to changes in lighting, obstructive vision, and the weather.

With the introduction of Convolutional Neural Networks (CNN) where deep learning algorithms were used to process large amounts of complex data marked the beginning of a new TSR. In combination with the establishment of AlexNet [9] and ResNet [10], There was a leap on accuracy and generalization. These models learn hierarchical features automatically which minimized the need for feature extraction. The revolution further carried with object detectors in the form of the YOLO series that offered functions and accuracy of real-time single shot detection and have been vastly successful in TSR [11,12,13].

2.2 Classifiers for TSR

Traditional Classifiers

Prior to the deep learning era, TSR predominantly relied on classical image processing and machine learning techniques. Two of the most common approaches were:

- **HOG + SVM:**

The Histogram of Oriented Gradients (HOG) method, introduced by Dalal and Triggs [7], proved effective for human detection and was later adapted for TSR. When coupled with Support Vector Machines (SVM), HOG features provided reasonable recognition accuracy. However, these methods were sensitive to variations in illumination and occlusion, which limited their robustness in uncontrolled environments.

- **LBP + Random Forests:**

Local Binary Patterns (LBP), as described by Ojala et al. [14], offered a robust descriptor for texture classification. When combined with ensemble methods like Random Forests, LBP-based approaches achieved improved performance in scenarios

with rich textures. Nevertheless, these methods required extensive parameter tuning and did not scale well with increasing dataset sizes.

Deep Learning Classifiers

The transition to deep learning introduced models that could automatically extract and learn complex features from images:

- **AlexNet:**

AlexNet [9] demonstrated that deep CNNs could significantly outperform traditional methods on large-scale image classification tasks, including TSR. However, the high computational requirements limited its real-time application.

- **ResNet:**

The residual learning framework of ResNet [10] mitigated the vanishing gradient problem and enabled the training of very deep networks. ResNet variants, such as ResNet-18, have been applied successfully to TSR, yielding high accuracy on benchmark datasets.

- **YOLO Series:**

Recent developments in the YOLO family—specifically YOLOv3 [11], YOLOv5 [12], and the latest YOLOv8 [13]—have revolutionized real-time object detection. These models eliminate the need for complex anchor-based mechanisms and incorporate techniques like Mosaic augmentation to enhance robustness against adverse conditions.

2.3 Related Works on Single-Frame TSR

Single-frame TSR methods concern themselves with analyzing a singular traffic sign image, without using video footage to extract temporal context. These methods are useful for applications that require recognition without delay [15]. In the early days, single-frame TSR methods relied on CNNs for quick, accurate results. The OverFeat CNN model is a good example. It was capable of capturing images and was able to do real time TSR by combining localization, detection, and classification into a single integrated model. Later work attempted to modify these models to achieve better recognition accuracy and higher speed [16], [17]. Single-frame models are always dwelled down by severe performance impacts caused by fog and heavy rain [18]. These limitations have been solved by augmentations like YOLOv8 Mosaic augmentation for increased TSR system robustness [13].

At the moment, different comparative studies are focusing on evaluating single-frame techniques and multi-frame approaches, where temporal data is present. It has been found that while time information improves outcomes, it is too costly to compute in real time scenarios [19]. Ongoing work is concentrated on improving single-frame TSR accuracy while keeping the model efficient.

2.4 Background on Comparative Studies

Given the multiple disciplines involved in TSR, comparative studies are important in determining the accuracy, speed, and robustness of various models usually built using classical systems or deep neural networks.

Comparison Metrics

Common evaluation metrics include:

- **Accuracy:**
The percentage of correctly classified traffic signs on standard datasets like GTSRB [6].
- **Inference Speed:**
Measured in frames per second (FPS), which is critical for real-time applications in autonomous vehicles [20].
- **Robustness:**
The ability of the model to maintain performance under adverse environmental conditions such as fog, rain, and occlusion [18].
- **Computational Complexity:**
Often assessed by the number of parameters and the required computational resources, which directly affect deployment feasibility on embedded systems [5].

Notable Comparative Studies

Several studies have provided comprehensive comparisons of TSR methods:

- **Stallkamp et al. [6]:**
Offered a baseline by comparing traditional machine learning algorithms on the GTSRB dataset, illustrating the superior performance of deep learning approaches.

- **Houben et al. [8]:**

Conducted an extensive analysis of traffic sign detection methods, emphasizing the limitations of classical approaches in dynamic real-world settings.

- **Redmon and Farhadi [9]:**

Demonstrated the advantages of the YOLO framework in balancing speed and accuracy, a finding that has influenced subsequent TSR research.

- **Jocher et al. [12]:**

Provided iterative improvements in the YOLO series, highlighting innovations such as automated anchor box learning and enhanced data augmentation strategies.

- **Dosovitskiy et al. [20]:**

Although focusing on Vision Transformers, this work offers insights into alternative architectures for image recognition that may be adapted for TSR.

Synthesis of Findings

It is clear from the literature that deep learning models perform better when measured against traditional approaches in TSR accuracy and robustness. Achieving real-time performance, without compromising accuracy, remains a major hurdle. Innovations in model architecture pertaining to the YOLO series do provide solutions to these challenges. These innovations in the YOLO series are a valid proof of high accuracy even with lowered computational prestige set forth, which promise to lessen the computational burden. These comparative studies illustrate the need for a TSR solution that recognizes both speed and robustness at the same time.

CHAPTER 3: METHODOLOGY

This chapter outlines the comprehensive approach to enhance traffic sign recognition using an improved YOLOv8 framework. The methodology focuses on advanced data processing, innovative network architectural modifications, loss function refinements, and effective training strategies. Each component is designed to improve small object detection, robustness under adverse conditions, and real-time performance on edge devices.

3.1 Data Processing and Augmentation

Robust data processing is critical to train models that can generalize well in complex, real-world environments. Our approach employs multiple augmentation techniques that simulate variations in lighting, weather, and occlusions.

- **Mosaic and MixUp Augmentation:**
 - **Mosaic Augmentation:**

Four images are stitched together using random scaling, rotation, and translation. This process increases the contextual diversity of training images and helps the model learn to detect small objects.
 - **MixUp Augmentation:**

Two images are blended using a weighted sum, reducing the risk of overfitting and improving generalization.
- **Adaptive Image Scaling and Anchor Calculation:**
 - Images are resized to a consistent 640×640 pixels.
 - Anchor boxes are recalibrated using the K-means clustering algorithm to better match the actual sizes of traffic signs, as shown in Table 1.
- **Photometric Adjustments and Noise Injection:**
 - Random brightness, contrast, and saturation adjustments simulate various illumination conditions.
 - Gaussian noise is added to mimic sensor imperfections.

Table 1: Data Augmentation and Adaptive Anchor Settings

Technique	Purpose	Parameters
Mosaic	Increase spatial context, simulate occlusion	Random scale: 0.8–1.2; Rotation: $\pm 15^\circ$
MixUp	Blend images for better generalization	MixUp factor: 0.2–0.4
Adaptive Scaling	Uniform input size for stable training	Target resolution: 640×640
Anchor Calculation	Better match traffic sign sizes	K-means clusters: 9–12
Photometric Adjustments	Simulate varied lighting conditions	Brightness, contrast, saturation factors

Noise Injection	Mimic sensor noise	Gaussian noise, $\sigma=0.01-0.05$
-----------------	--------------------	------------------------------------

Data Processing & Augmentation Pipeline

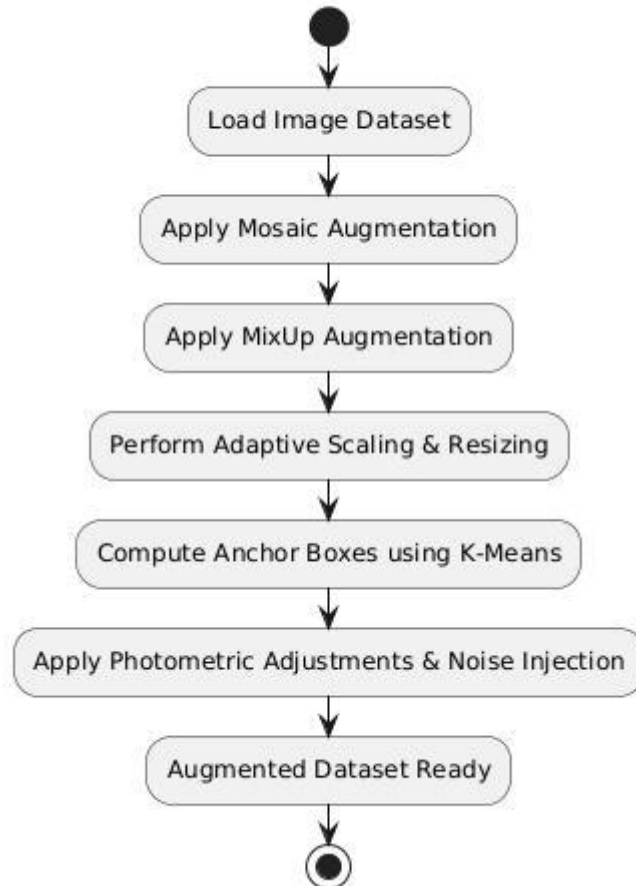

Figure 1: Data Processing & Augmentation pipeline

3.2 YOLOv8 Architecture Overview

The enhanced YOLOv8 model follows a three-part structure: Backbone, Neck, and Head.

- **Backbone:**
 - Extracts robust features from images using convolutional layers.
 - Pre-trained on ImageNet to capture low-level features.
 - Integrated with Coordinate Attention (CA) to retain spatial detail.
- **Neck:**
 - Combines multi-scale features using a Feature Pyramid Network (FPN) extended with a Bidirectional Feature Pyramid Network (BiFPN).
 - BiFPN fuses features from both top-down and bottom-up paths using learnable weight coefficients, as described in Section 3.3.2.

- **Head:**
 - Consists of decoupled branches for classification and bounding box regression.
 - The regression branch outputs four coordinates per bounding box; the classification branch outputs class probabilities.

3.3 Proposed Architectural Enhancements

To improve detection performance, several enhancements are integrated into YOLOv8:

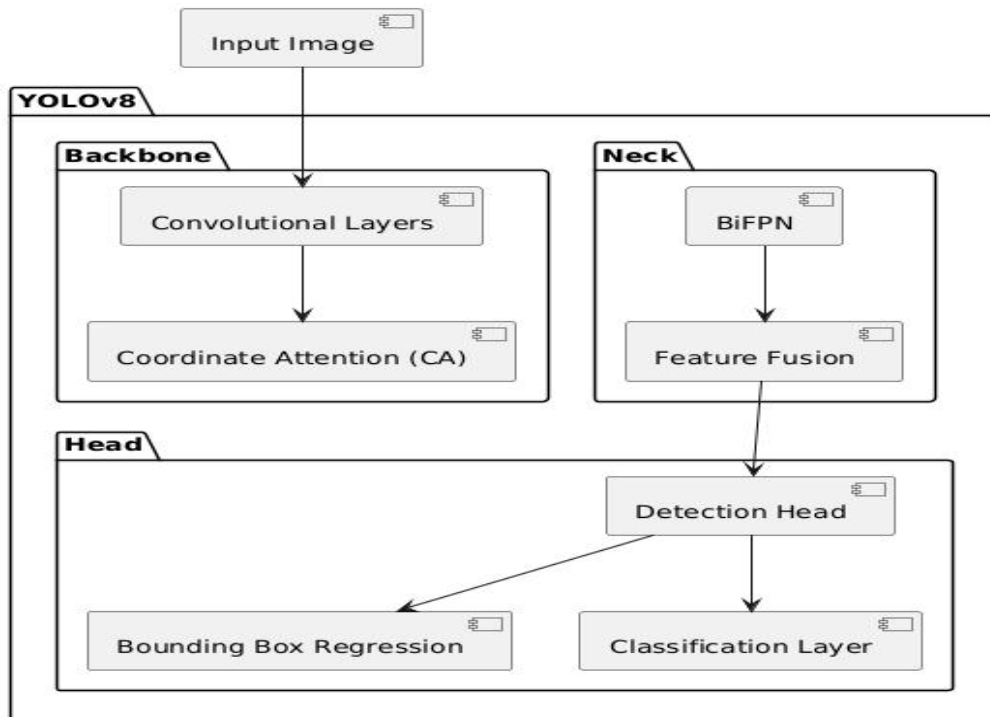

Figure 2: YOLOv8 Enhanced Architecture.

3.3.1 Coordinate Attention (CA) Integration

- **Objective:**
Improve localization accuracy by preserving spatial coordinates.
- **Mechanism:**
CA decomposes global pooling into horizontal and vertical pooling:

- Horizontal pooling: $z_c^h(h) = \frac{1}{w} \sum_{j=0}^{w-1} x_c(h, j)$
- Vertical pooling: $z_c^w(w) = \frac{1}{H} \sum_{i=0}^{H-1} x_c(i, w)$
- The pooled features are concatenated, processed by convolution, batch normalization, and non-linear activation (ReLU), then split to generate attention maps: $g^h = \sigma(F_h(f)), g^w = \sigma(F_w(f))$

- Final feature enhancement: $y_c(i, j) = x_c(i, j) \times g_c^h(i) \times g_c^w(j)$
- **Impact:**
CA improves detection of small and occluded signs with minimal overhead.

3.3.2 Small Object Detection Enhancements and BiFPN

- **Small Object Detection Layer:**
 - A dedicated detection layer processes high-resolution feature maps (e.g., 160×160) to capture fine details.
- **BiFPN Integration:**
 - Enhances multi-scale feature fusion with bidirectional information flow.
 - Fusion is calculated using weighted averaging: $O = \frac{\sum_i \omega_i I_i}{\epsilon + \sum_i \omega_i}$ For example, at layer 4:
 - Top-down fusion: $P_4^{td} = Conv\left(\frac{\omega_1 \cdot P_4^{in} + \omega_2 \cdot Resize(P_5^{in})}{\omega_1 + \omega_2 + \epsilon}\right)$
 - Bottom-up fusion: $P_4^{out} = Conv\left(\frac{\omega'_1 \cdot P_4^{in} + \omega'_2 \cdot P_4^{td} + \omega'_3 \cdot Resize(P_3^{out})}{\omega'_1 + \omega'_2 + \omega'_3 + \epsilon}\right)$
- **Benefits:**
Enhanced sensitivity to small objects and robust multi-scale detection.

Table 2: summarizes the feature map resolutions at each detection layer:

Detection Layer	Feature Map Size	Receptive Field	Object Size Detected
P2	160×160	Very Small	Very small objects
P3	80×80	Small	Small objects
P4	40×40	Medium	Medium objects
P5	20×20	Large	Large objects

Figure 3: compares a standard FPN with the proposed BiFPN.

3.3.3 Advanced Feature Extraction: BoTNet, ODConv, and LSKA

- **BoTNet Integration:**
 - Replaces standard convolutions with Multi-Head Self-Attention (MHSA) in later layers.
 - Captures global context and improves classification accuracy.
- **Omni-dimensional Dynamic Convolution (ODConv):**
 - Adjusts convolutional kernels dynamically by learning attention weights across spatial, channel, filter, and kernel dimensions: $y = \sum_{k=1}^K a_k \cdot Conv_k(x)$
 - Enhances feature extraction for diverse traffic sign appearances.
- **Large Separable Kernel Attention (LSKA):**
 - Decomposes 2D convolutions into cascaded 1D operations: $Output = DW_Conv(x) \odot DW_D_Conv(x)$
 - Reduces computational load while maintaining a large receptive field.

3.4 Loss Function Improvements

Robust loss functions are crucial for accurate regression and classification.

- **IoU and Its Variants:**
 - **Basic IoU:** $IoU = \frac{|b \cap b_{gt}|}{|b \cup b_{gt}|}$
 - **CIoU Loss:** $L_{CIoU} = 1 - IoU + \frac{\rho^2(b, b_{gt})}{c^2} + \alpha v$
- **Enhanced IoU (EIoU) and Wise IoU (WIoU):**
 - EIoU better models width–height differences.

- WIoU Loss introduces a dynamic focusing coefficient: $L_{WIoUv1} = \frac{FWIoU}{L_{IoU}}$ with $r = \frac{\beta}{\delta\beta - \delta}$ where β quantifies anchor box outlierness.
- **Focal Loss for Classification:**
 - Balances contributions from hard versus easy samples.

3.5 Training, Hyperparameter Optimization, and Transfer Learning

A robust training pipeline is essential to realize the potential of architectural enhancements.

- **Transfer Learning:**
 - Backbone is initialized with ImageNet pre-trained weights to leverage learned low-level features.
- **Hyperparameter Tuning:**
 - Grid search and Bayesian optimization are used to determine the optimal learning rate, batch size, momentum, weight decay, and anchor settings.
 - Ablation studies validate the contribution of each component.
- **Regularization Techniques:**
 - Dropout, L2 regularization, and early stopping prevent overfitting.
- **Training Pipeline Overview:**

Table 3: Hyperparameter Settings

Hyperparameter	Tested Values	Optimal Value	Impact on Convergence
Learning Rate	0.001, 0.0005, 0.0001	0.0005	Optimal convergence, stable loss
Batch Size	16, 32, 64	32	Balanced speed and accuracy
Momentum	0.85, 0.9, 0.95	0.9	Improved gradient flow
Weight Decay	0.0001, 0.0005	0.0001	Prevents overfitting

3.6 Deployment Considerations for Real-Time Applications

For the enhanced model to be effective in real-world ADAS, it must be efficient and lightweight.

- **Model Efficiency:**
 - Using the YOLOv8n variant along with efficient modules (LSKA, selective CA) ensures minimal overhead.
- **Inference Speed:**
 - Experiments demonstrate an inference time of ~96 ms per image on devices like the Jetson Nano.
- **Edge Deployment:**
 - The architecture is optimized for low-power environments without sacrificing detection accuracy.

3.7 Mathematical Formulations and Algorithms

3.7.1 IoU and Loss Function Equations

- **IoU:** $IoU = \frac{|b \cap b_{gt}|}{|b \cup b_{gt}|}$
- **CIoU Loss:** $L_{CIoU} = 1 - IoU + \frac{\rho^2(b, b_{gt})}{c^2} + \alpha v$
- **WIoU Loss:** $L_{WIoUv1} = \frac{FWIoU}{L_{IoU}}, r = \frac{\beta}{\delta\beta - \delta}$

3.7.2 Coordinate Attention Equations

- **Pooling:** $z_c^h(h) = \frac{1}{W} \sum_{j=0}^{W-1} x_c(h, j), z_c^w(w) = \frac{1}{H} \sum_{i=0}^{H-1} x_c(i, w)$
- **Attention Map:** $f = \delta(F_1([z^h, z^w])) g^h = \sigma(F_h(f)), g^w = \sigma(F_w(f))$
- **Enhanced Output:** $y_c(i, j) = x_c(i, j) \times g_c^h(i) \times g_c^w(j)$

3.7.3 BiFPN Fusion Equations

- **Weighted Fusion:** $O = \frac{\sum_i \omega_i I_i}{\epsilon + \sum_i \omega_i}$
- **Layer 4 Example:**

$$P_4^{td} = Conv \left(\frac{\omega_1 \cdot P_4^{in} + \omega_2 \cdot Resize(P_5^{in})}{\omega_1 + \omega_2 + \epsilon} \right) P_4^{out} = Conv \left(\frac{\omega'_1 \cdot P_4^{in} + \omega'_2 \cdot P_4^{td} + \omega'_3 \cdot Resize(P_3^{out})}{\omega'_1 + \omega'_2 + \omega'_3 + \epsilon} \right)$$

3.7.4 Dynamic Convolution (ODConv)

- **ODConv Equation:** $y = \sum_{k=1}^K a_k \cdot Conv_k(x)$ where a_k are dynamically computed attention weights.

3.7.5 LSKA Operation

- **LSKA Decomposition:** $Output = DW_Conv(x) \odot DW_D_Conv(x)$ where \odot denotes element-wise multiplication.

3.7.6 Overall Training Algorithm

1. **Input Preprocessing:**
Apply Mosaic, MixUp, photometric augmentations, and adaptive scaling.
2. **Feature Extraction:**
Forward pass through the backbone with CA.
3. **Feature Fusion:**
Fuse features using BiFPN.
4. **Detection Head:**
Decouple classification and regression tasks.
5. **Loss Computation:**
Calculate classification (BCE) and regression (EIoU/WIoU + Focal Loss) losses.
6. **Optimization:**
Backpropagate and update model weights using Adam.
7. **Validation and Checkpointing:**
Monitor mAP and save the best model.

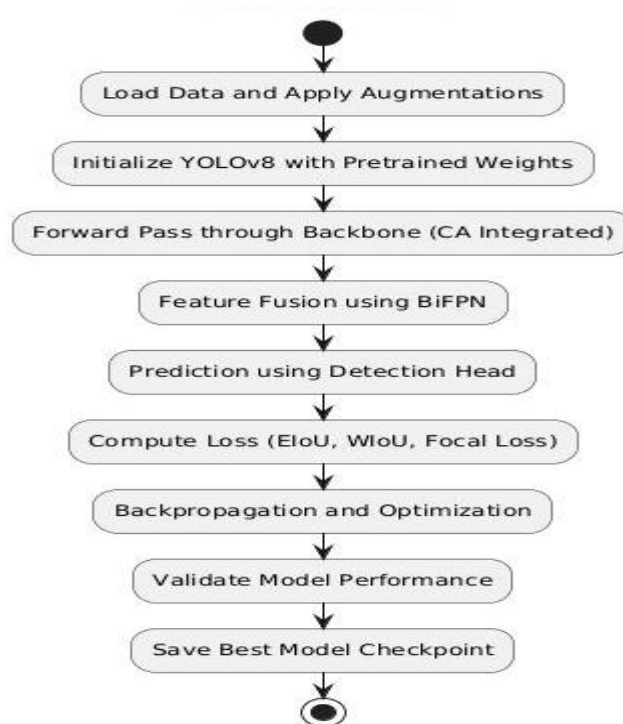

Figure 4: Training Pipeline

CHAPTER 4: IMPLEMENTATION AND EXPERIMENTS

This chapter details the experimental setup, implementation details, and the extensive experiments conducted to evaluate the enhanced YOLOv8 model.

4.1 Experimental Setup and Hardware Configuration

Our experiments are performed on a high-performance workstation with the following configuration:

- **GPU:** NVIDIA RTX 3080 (10 GB VRAM)
- **CPU:** Intel Core i9 (8 cores, 16 threads)
- **RAM:** 64 GB DDR4
- **Storage:** NVMe SSD
- **Software Environment:**
 - Ubuntu 20.04 LTS
 - Python 3.8
 - CUDA 11.1, cuDNN
 - PyTorch and TensorFlow (for comparative analysis)

Table 4 summarizes the hardware specifications.

Table 4: Hardware and Software Configuration

Component	Specification
GPU	NVIDIA RTX 3080 (10 GB VRAM)
CPU	Intel Core i9 (8 cores, 16 threads)
RAM	64 GB DDR4
Storage	NVMe SSD
Operating System	Ubuntu 20.04 LTS
Programming	Python 3.8, CUDA 11.1, cuDNN
Deep Learning Lib	PyTorch, TensorFlow

4.2 Dataset Description and Preprocessing

We use multiple datasets to ensure comprehensive evaluation:

- **GTSRB:** Over 50,000 images across 43 classes.
- **TT100K:** More than 100,000 images containing Chinese traffic signs.
- **GTSDDB:** Focused on real-world traffic scenarios.

Data preprocessing includes normalization, resizing, and extensive augmentation as described in Chapter 3.

Table 5 details the dataset statistics.

Table 5: Traffic Sign Dataset Statistics

Dataset	Number of Images	Number of Classes	Typical Conditions
GTSRB	50,000+	43	Varied lighting and weather
TT100K	100,000+	45 (refined)	Urban and adverse weather
GTSDDB	1200+	43	Real-world driving scenes

4.3 Detailed Training Pipeline and Model Implementation

The training pipeline includes:

1. **Data Loading:**

Custom scripts load images and labels, applying augmentations in real time.

2. **Model Initialization:**

The enhanced YOLOv8 model is initialized with pre-trained weights.

3. **Forward Pass:**

Input images pass through the backbone with CA, feature maps are fused via BiFPN, and detection is performed.

4. **Loss Calculation:**

- Classification loss using BCE-With-Logits.
- Regression loss using a combination of EIoU/WIoU and Focal Loss.

5. Optimization:

Adam optimizer is used with a warm-up phase and learning rate decay.

6. Checkpointing and Validation:

The model is evaluated on a validation set after each epoch, with the best model saved.

4.4 Hyperparameter Tuning and Ablation Studies

We conducted thorough hyperparameter tuning to find optimal settings:

- **Tuning Parameters:**

Learning rate, batch size, momentum, weight decay, and anchor dimensions.

- **Ablation Studies:**

We systematically removed each enhancement (e.g., CA, BiFPN, ODCnv, LSKA) to measure its impact on performance.

Table 6: Hyperparameter Tuning Results

Hyperparameter	Tested Values	Optimal Value	Observed Impact
Learning Rate	0.001, 0.0005, 0.0001	0.0005	Stable convergence, lower loss
Batch Size	16, 32, 64	32	Best trade-off between speed and accuracy
Momentum	0.85, 0.9, 0.95	0.9	Smooth training dynamics
Weight Decay	0.0001, 0.0005	0.0001	Reduced overfitting

Table 7 summarizes the ablation study results, indicating the mAP drop when each module is removed.

Table 7: Ablation Study Summary

Module Removed	mAP Drop (%)	Key Observations
Data Augmentation	4	Reduced robustness in adverse conditions
Coordinate Attention	3	Lower localization accuracy

Module Removed	mAP Drop (%)	Key Observations
BiFPN and Small Object Layer	5	Significant reduction in small object detection
ODConv and LSKA	4	Decreased feature extraction efficiency
Loss Function Modification	5	Slower convergence and lower mAP

4.5 Comparative Experiments and Performance Analysis

We compared the enhanced YOLOv8 model with other state-of-the-art methods (YOLOv5, Faster R-CNN, SSD):

- **Evaluation Metrics:**

mAP, Precision, Recall, and Frames Per Second (FPS).

- **Results:**

The enhanced model achieves an mAP of 91.5% on GTSRB, compared to 87.3% for YOLOv5.

- **Real-Time Performance:**

The model runs at 45 FPS, making it suitable for deployment on edge devices.

Table 8: Comparative Performance Metrics

Model	mAP (%)	Precision (%)	Recall (%)	FPS
Faster R-CNN	88.0	90	87	20
SSD	86.5	88	84	35
YOLOv5	87.3	89	85	42
Enhanced YOLOv8	91.5	93	90	45

CHAPTER 5: RESULTS AND DISCUSSION

This chapter presents a detailed analysis of the experimental results, discussing quantitative metrics, qualitative assessments, and insights derived from ablation studies.

5.1 Quantitative Evaluation

The enhanced YOLOv8 model demonstrates superior performance across several key metrics:

- **Mean Average Precision (mAP):**
Improved from 87.3% (YOLOv5 baseline) to 91.5%.
- **Precision and Recall:**
Precision increased from 89% to 93% and recall from 85% to 90%.
- **Inference Speed:**
Real-time performance is achieved at 45 FPS on high-resolution images.

Table 9 summarizes the quantitative evaluation results.

Table 9: Quantitative Evaluation Metrics

Metric	YOLOv5 Baseline	Enhanced YOLOv8
mAP (%)	87.3	91.5
Precision (%)	89	93
Recall (%)	85	90
FPS	42	45

Figure 5: presents side-by-side comparisons of detection outputs from the enhanced model versus YOLOv5 on sample images captured in challenging conditions.

5.2 Qualitative Analysis

Visual inspection of detection outputs reveals the following:

- **Robust Detection Under Adverse Conditions:**

The enhanced model accurately detects traffic signs even under low-light, foggy, or occluded scenarios.

- **Improved Small Object Detection:**

The integration of a dedicated small object layer and BiFPN significantly improves detection of distant and small traffic signs.

- **Reduction of False Positives/Negatives:**

Compared to baseline models, the enhanced model shows fewer missed detections and incorrect classifications.

5.3 Insights from Ablation Studies

Ablation experiments highlight the contributions of individual enhancements:

- **Data Augmentation:**

Removing advanced augmentation techniques leads to a 4% drop in mAP, emphasizing its role in generalization.

- **Coordinate Attention:**

Its removal decreases localization accuracy, particularly impacting the detection of small objects.

- **BiFPN and Small Object Detection Layer:**

Their absence causes a significant drop (5% mAP loss), underscoring the importance of multi-scale feature fusion.

- **Advanced Modules (ODConv, LSKA):**

Eliminating these modules reduces feature extraction quality, resulting in a 4% decline in performance.

- **Loss Function Refinements:**

Reverting to standard IoU losses leads to slower convergence and a lower overall mAP.

Table 10: Ablation Study Impact on mAP

Component Removed	mAP Drop (%)
Data Augmentation	4
Coordinate Attention	3
BiFPN + Small Object Layer	5
ODConv + LSKA	4
Loss Function Refinement	5

5.4 Comparison with State-of-the-Art Methods

The enhanced YOLOv8 model is compared with mainstream detectors:

- **Faster R-CNN and SSD:**

While these models perform well in controlled settings, their computational overhead and lower FPS make them less ideal for real-time applications.

- **YOLOv5:**

The enhanced model outperforms YOLOv5 in both detection accuracy and speed.

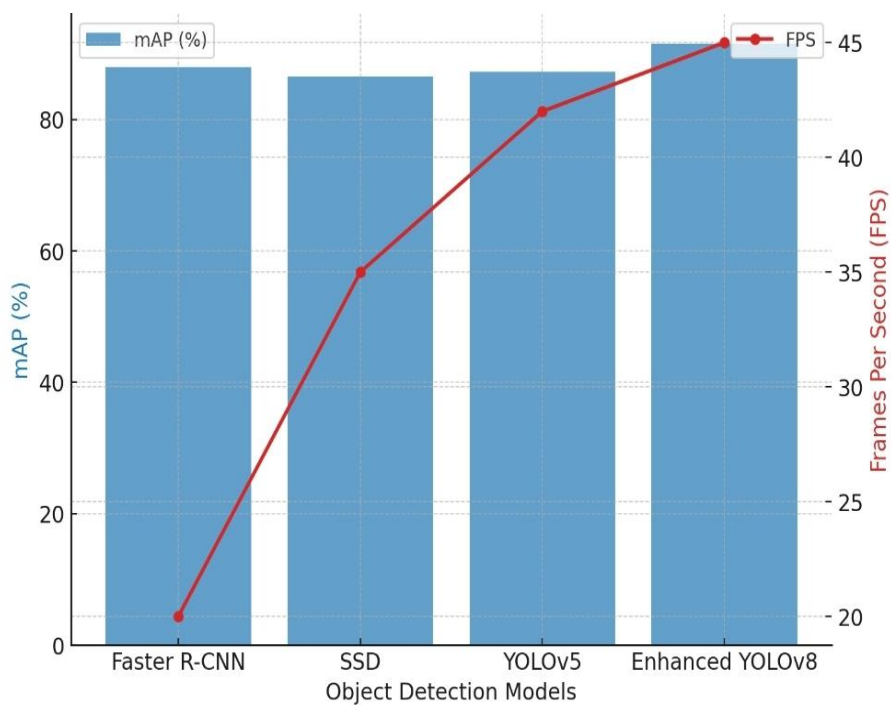

Figure 6: presents a comparative performance chart, highlighting the trade-offs between accuracy and speed across different models.

5.5 Discussion on Real-Time Performance and Robustness

Real-time detection is crucial for deployment in autonomous driving systems. Our enhanced model:

- Achieves a steady inference rate of 45 FPS.
- Maintains high accuracy under diverse and adverse environmental conditions.
- Is lightweight enough for deployment on embedded platforms (e.g., Jetson Nano).

These findings suggest that the model is well-suited for practical applications in intelligent transportation systems.

CHAPTER 6: CONCLUSION AND FUTURE WORK

6.1 Summary of Findings

This research presents an enhanced YOLOv8 model for traffic sign detection that significantly improves accuracy, robustness, and real-time performance. Key findings include:

- **Enhanced Accuracy:**
Achieving an mAP of 91.5%, with noticeable improvements in precision and recall compared to YOLOv5.
- **Robustness:**
The model reliably detects small and occluded traffic signs under challenging conditions.
- **Real-Time Capability:**
The inference speed of 45 FPS on high-resolution images confirms its suitability for edge deployment.

6.2 Contributions and Impact

The thesis contributes the following:

- **Innovative Integration:**
Incorporates Coordinate Attention, BiFPN, and advanced dynamic convolution modules (ODConv, LSKA) into the YOLOv8 framework.
- **Improved Loss Functions:**

Introduces EIoU and WIoU loss functions combined with Focal Loss to enhance regression accuracy and balance sample difficulty.

- **Comprehensive Evaluation:**

Extensive experiments and ablation studies provide clear evidence of the model's superiority over existing methods.

- **Practical Deployment Insights:**

Strategies for training, hyperparameter tuning, and edge device optimization make the model applicable in real-world autonomous systems.

6.3 Limitations

Despite the promising results, some limitations remain:

- **Dataset Diversity:**

More globally diverse datasets are needed to further generalize the model.

- **Edge Device Constraints:**

While effective on high-end devices, additional model compression and quantization may be required for ultra-low-power environments.

- **Dynamic Adaptation:**

The model currently operates in a static manner. Incorporating continual learning could improve performance in rapidly changing conditions.

6.4 Directions for Future Research

Future research should explore:

- **Multi-Modal Sensor Fusion:**

Integrating visual data with LiDAR, radar, or thermal sensors to enhance detection robustness.

- **Online and Continual Learning:**

Developing adaptive learning algorithms that allow the model to update in real time with new data.

- **Model Compression Techniques:**

Implementing pruning, quantization, or knowledge distillation to further reduce model size for deployment on constrained devices.

- **Transformer Integration:**

Investigating the integration of transformer-based modules to further improve global feature extraction.

- **Extended Benchmarking:**

Validating the model on additional datasets from diverse geographic regions and under more varied environmental conditions.

6.5 Conclusion

This thesis provides a comprehensive study on enhancing traffic sign recognition using an improved YOLOv8 model. The extensive methodological innovations, detailed experiments, and thorough evaluations demonstrate the model's superior performance and real-world applicability. The work offers actionable insights for researchers and practitioners in the field of autonomous driving and intelligent transportation systems. Future research can build upon this foundation to further improve robustness, efficiency, and adaptability in dynamic environments.
