# DSM: Building A Diverse Semantic Map for 3D Visual Grounding

Qinghongbing Xie<sup>1†</sup>, Zijian Liang<sup>2†</sup> and Long Zeng<sup>1\*</sup> Project Page: https://binicey.github.io/DSM

Abstract-In recent years, with the growing research and application of multimodal large language models (VLMs) in robotics, there has been an increasing trend of utilizing VLMs for robotic scene understanding tasks. Existing approaches that use VLMs for 3D Visual Grounding tasks often focus on obtaining scene information through geometric and visual information, overlooking the extraction of diverse semantic information from the scene and the understanding of rich implicit semantic attributes, such as appearance, physics, and affordance. The 3D scene graph, which combines geometry and language, is an ideal representation method for environmental perception and is an effective carrier for language models in 3D Visual Grounding tasks. To address these issues, we propose a diverse semantic map construction method specifically designed for robotic agents performing 3D Visual Grounding tasks. This method leverages VLMs to capture the latent semantic attributes and relations of objects within the scene and creates a Diverse Semantic Map (DSM) through a geometry slidingwindow map construction strategy. We enhance the understanding of grounding information based on DSM and introduce a novel approach named DSM-Grounding. Experimental results show that our method outperforms current approaches in tasks like semantic segmentation and 3D Visual Grounding, particularly excelling in overall metrics compared to the stateof-the-art. In addition, we have deployed this method on robots to validate its effectiveness in navigation and grasping tasks.

#### I. INTRODUCTION

Scene representation is crucial for robotic agents to perform tasks in real-world environments, as it serves as the fundamental carrier for acquiring and understanding environmental information. It also acts as the primary source of information for 3D Viusal Grounding. For example, when a service robot retrieves a fruit from a refrigerator in a room, it must first acquire the type and existence of the fruit, as well as its associations with other objects in the room.

Previous research has primarily focused on visual understanding from the perspective of viewpoint selection, employing more precise and adaptive observation methods for different objects. However, these approaches often overlook the diverse attributes of objects and the potential interrelationships between them, which could provide robotic agents with rich implicit logic. For example, *knowing that a red apple is stored in a refrigerator while a green apple is placed in a basket on a table* offers deeper insights for a robot searching for a potentially sweeter apple.

Fig. 1. Our work introduces a novel scene representation, the Diverse Semantic Map (DSM), designed to enhance semantic perception and deep reasoning in the 3D Visual Grounding task.

This type of contextual environmental information is highly diverse and complex. For example, an apple's color, freshness, weight, size, and position are all critical for robotic task execution. However, effective information representation must encode the richest information with the fewest dimensions to be adaptable to various robotic agents. Therefore, we propose a novel scene representation called the Diverse Semantic Map (DSM), which incorporates multidimensional object attributes and relationships between objects for 3D Visual Grounding. To address these challenges, our method introduces a novel approach that leverages Vision-Language Models (VLMs) to construct a multi-dimensional semantic map. This map represents both the geometric features and implicit semantic attributes of the scene, including appearance, physical, and affordance attributes. By providing richer, more nuanced scene understanding, DSM enhances the adaptability and effectiveness of robotic systems.

Continuous-time sampling from a first-person perspective is the most common data gathered when a robot executes actions. It provides a causal relationship in the perception of object geometry and semantic attributes. Thus, our approach introduces a novel time-window-based 3D Scene Graph construction method. This method extracts multi-view semantics from continuous-time observations to construct both object geometry and semantic attributes for DSM.

Complex spatial information poses a significant challenge to the understanding capabilities of VLMs. However, through a multi-step process of reasoning and filtering, we can significantly enhance VLMs' ability to understand scenes. Therefore, we utilize the diverse semantic information provided by DSM for selecting candidate objects and filter potential

candidates using relationships between objects. We then perform multi-level visual observations on the final candidate objects, proposing a DSM-based visual grounding method, termed DSM-Grounding.Compared to previous state-of-theart methods, DSM-Grounding significantly improves the success rate of 3D Visual Grounding for objects within a scene. Additionally, we have applied this method to tasks such as robot navigation and grasping, validating its high performance and practicality.

In summary, we propose a Diverse scene representation structure DSM for 3D Visual Grounding, and we have developed a time-window-based mapping method for geometric and semantic perception of the scene to establish DSM. Finally, based on DSM, we introduce a novel 3D grounding method for enabling robot understanding of scene information.

# Our main contributions are as follows:

- 1) We proposed a Diverse 3D semantic map structure DSM for 3D Visual Grounding.
- 2) We constructed a time-window-based semantic mapping construction method for DSM.
- 3) We develop a novel 3D Visual Grounding Method based on DSM.

## II. RELATED WORK

3D Scene Representation The precise and persistent perception of the surrounding environment through sensors is crucial for the autonomous operation of robots.[1] Previous works such as ORB-SLAM2[2], NICE-SLAM[3], and GradSLAM[4] focus more on the accurate scale information in the environment, which is used for robot localization and dynamic control. With the development of neural networks, representation methods that combine scale information and semantic information from the environment have gradually emerged, such as Kimera<sup>[5]</sup> and ConceptFusion<sup>[6]</sup>. These methods extract visual semantics through detection segmentation models and integrate them into the scene geometric map for perception and environmental understanding of autonomous robots in small-scale scenes. As the challenges of large-scale scenes and long-sequence tasks have been raised, scene representation methods have increasingly focused on analyzing relationships between objects while constructing both geometry and object semantics, i.e., building 3D scene graphs, such as SceneGraphFusion[7] and Hydra[8]. With the deepening application of large language models, the use of large models for open vocabulary construction without annotations has been proposed, such as ConceptGraphs[9], Clio[10], etc. Compared with the first two 3D representation methods, 3DSG can represent the scene more concisely, making it easier for robots to perceive environmental information.

**3D Scene Graph** 3D scene understanding is difficult to represent effectively because objects form various relationships and continuously interact with each other. Scene graphs are a powerful tool for succinctly representing object attributes and relationships within a scene, enabling a wide range of multimodal tasks[11]. Supervised 3D Scene Graph methods, such as 3D Dynamic Scene Graphs[12] and SceneGraphFusion[7], focus on how to efficiently and quickly extract object names and semantic relationships from the scene. With the gradual development of large language models, unsupervised methods based on large language models[13], [9], [14] have applied the general perceptual abilities of large language models to the construction of 3DSG, achieving two major features: zero-shot and openvocabulary. However, existing work is unable to support scene perception for complex robotic tasks that require deep reasoning, especially when dealing with complex object attributes and the implicit relationships between objects.

3D Visual Grounding The 3D Visual Grounding task refers to the alignment or connection between natural language text and 3D visual scenes, in order to achieve crossmodal understanding and interaction. Open-vocabulary and zero-shot methods, such as OpenScene[15], OVIR-3D[16], Open3DIS[17], utilize cross-modal feature spaces to handle open vocabulary tasks without the need for predefined categories and large amounts of labeled data. Multimodal reasoning and interaction methods, such as SeeGround[18], ScanReason[19], ScanERU[20], and LanguageRefer[21], combine the understanding and reasoning capabilities of multimodal large models with human-machine interaction observation methods to enhance understanding of 3D scenes. These methods particularly show better generalization when dealing with multiple similar objects or complex instructions. However, existing methods often only understand and reason about images or point clouds within the scene, making it difficult to obtain deeper information from the scene.

In order to overcome the limitations of existing 3D visual grounding methods in understanding and reasoning deep scene information, a more comprehensive understanding of spatial relationships need to be provided by enhancing semantic representation and multi-view fusion technology, while combining Large Multimodal Models(LMMs) to improve the understanding of complex instructions and the reasoning ability of implicit information.

#### III. METHOD

In this work, we address the challenge of enabling robots to comprehend complex information for 3D Visual grounding and apply it to robotic agents by constructing a Diverse Semantic Map (DSM), which consists of an object-based geometry map (DSM - G) and a multi-dimensional semantic map (DSM - S). We utilize the information perceived by the robot for semantic extraction and filtering, constructing a grounding method based on DSM, DSM - Grounding. Our pipeline is illustrated in Figure 2.

In III-B and III-C, we describes in detail how to construct DSM, including DSM - G and DSM - S. In III-D, we discuss the construction details of DSM - Grounding based on DSM.

## A. Definition of DSM

For the time-continuous frame sequence  $I = \{i_t | t \in \{1, ..., N\}\}$  captured within a scene, we assume that each frame's color image, depth image and positional information are provided, denoted as

Fig. 2. **Overview of the DSM framework**. After receiving the user's query, the robot first collects time-continuous poses, depth images, and color images of the scene to build a DSM. Next, we extract the visual and geometric information from each observation point. At the same time, we use VLM to analyze their relationships and semantic attributes, which are categorized into Appearance, Physical and Affordance Attributes. We fuse objects from multi views using a multimodal object fusion method in conjunction with the Geometry Sliding Window method for mapping. Finally, we identify candidates in the DSM based on the attributes and relationships of objects. We use the multi-level observations method to precisely locate the target object. Additionally, our method can be broadly applied to tasks such as robotic semantic navigation and semantic grasping.

 $i_t = \{\text{color}_t, \text{depth}_t, \text{pose}_t\}$ . Leveraging this information, we construct a comprehensive 3D semantic map that integrates both geometric and semantic elements, termed the Diverse Semantic Map (DSM). This DSM is composed of two primary components: the geometric map and the semantic map.

The object-based geometry map DSM - G includes geometric semantic information of Objects  $O_g$  including 3D bounding boxes  $bbox_{3d}$  and point clouds pcd,  $O_g = \{bbox_{3d}, pcd\}$ , representing position, volume, appearance and shape, as well as the geometric relationships  $R_g$  between objects in the scene, including distance and location descriptions.

The semantic map DSM - S contains the semantic descriptions of objects  $O_s$ , including appearance attributes  $a_a$ , physical attributes  $a_p$ , and affordance attributes  $a_o, O_s = \{a_a, a_p, a_o\}$ , Furthermore, it includes hybrid semantic relationships,  $R_s$ , such as ownership and functional relationships between objects.

#### B. Single View Parsing

Visual and Geometry Detection. We employ an openvocabulary detection model to detect objects within each frame, yielding 2D bounding boxes. Subsequently, a promptbased segmentation model is utilized to segment the detected objects, resulting in color-based segmentations $se_{g_c}$ . We map the depth image into color space, repeat the segmentation of this colorized depth image to obtain depth-based segmentation  $seg_d$ .By computing the intersection of these two segmentations, we derive the final segmentation result seg = $seg_c \cap seg_d$ . Based on segmentation and camera parameters, we extract the point cloud of object pcd in the current frame. To integrate 3D information, we perform feature extraction on the segmentation by using a visual encoder to extract the hidden features  $f_v$ . We define all detection information collected at time t as  $D_t$ .

**Semantic Caption**. According to the range of information perceived by the robot in a scene task, we categorize the semantic information of the scene into three dimensions:

- Appearance attribute *a<sub>a</sub>*: Describes the visual characteristics of objects, including color, patterns, and texture.
- **Physical attribute** *a<sub>p</sub>*: Captures the physical properties of objects, such as weight, material composition, and surface smoothness.
- Affordance attribute *a<sub>o</sub>*: Defines the functional aspects, applications, and operational methods associated with objects.

For semantic relations, We consider that the ownership and functional relationships, such as *the sofa and the coffee table together constitute the resting area of the living room, and while resting on the sofa, one can place items on the coffee table*, represent the implicit semantic relationships between objects, which are crucial for the robot to perform multiobject tasks and logical reasoning over long sequences of actions.

Therefore, We design a method based on visual prompts[22] and CoT[23] to extract semantic attributes and semantic relationships of the current frame using VLMs. We using a text encoder to extract the sematic feature  $f_s$  from all semantic attributes. The result example is shown in Table I and Table II.We define all detection information collected at time t as  $C_t$ .

| TABLE I                       |

| Anchor      | sofa   | close by         | for comfort and support<br>while sitting or lounging. |

# C. Multi View Mapping

**Multimodal Object Fusion**. The perception of robots within a scene is often object-centric. Previous works, such as ConceptGraphs [6], have also utilized objects as the basic unit for constructing maps, facilitating practical applications for robots. Therefore, we also use objects as the fundamental units for constructing maps. During the map construction process, we update the attributes of objects in real-time based on  $D_t$  and  $C_t$ .

Assume that at time t and t + 1, for  $Op_t$  and  $\hat{O}q_{t+1}$ , we use the features extracted from Detection and Caption to compute the visual similarity score  $s_v$ , geometric similarity score  $s_g$ , and semantic similarity score  $s_c$ . We calculate the fused similarity score S between p and  $\hat{q}$  as follows:

$$S = s_v + s_g + s_c \tag{1}$$

$$s_{\nu} = \text{CosSimilarity}(f_{\nu\hat{p}}, f_{\nu\hat{q}})$$
(2)

$$s_g = \begin{cases} s_{g0} & \text{if } bbox_p \text{ inside } bbox_q \\ \text{IoU}(bbox_p, bbox_q) & \text{otherwise} \end{cases}$$
(3)

$$s_c = \text{CosSimilarity}(f_{s\hat{p}}, f_{s\hat{q}}) \tag{4}$$

To enhance the robustness of the fusion process, we first apply similarity filtering to  $s_v$ ,  $s_g$ , and  $s_c$ . If any of these scores fall below a predefined threshold,  $Op_t$  and  $\hat{Oq}_{t+1}$  are not considered the same object. After filtering by thresholds, two objects with a total similarity greater than  $S_0$  are the same object and they are fused to form Op.

**Geometry Sliding Window Mapping**. For the input timecontinuous data D and contextual information C, we define a time window T. At any given time t, suppose there is a point cloud observation  $pcd_t$  of an object O from the observation point  $v_t$ . For each observation, we use the Monte Carlo sampling method to calculate the bounding sphere  $sp_t$  of the point cloud, and then construct the circumscribed  $Cone_t$  with respect to the bounding sphere Q, which represents the observation cone for the object at  $v_t$ .

After obtaining the *T* observation cones in the time window, we use a voting mechanism to filter the point cloud. Initially, all point cloud fragments within the time window are fused to obtain a consolidated point cloud  $P_T$ . Then, we compare the point cloud with the set of observation cones and perform voting. Points inside the observation cone receive a vote  $r_{in}$ , while points outside the cone receive a deduction  $r_{out}$ . Finally, all point clouds with scores greater than 0 are retained as the fused point cloud. The mapping process is shown in Figure 3.

As time progresses, the geometric map will be gradually optimized and updated, while the semantic relationships will also be progressively updated. We will correspond the filtered points, semantic relationships, and semantic attributes using the point cloud occupancy method. As the point cloud associated with semantic information gradually decreases, its corresponding weight will also gradually decrease. Conversely, the semantic information and relationships represented by the point cloud with the highest occupancy will become the final semantic attributes of the object.

Fig. 3. Geometry Sliding Window Method. We first employ the Monte Carlo sampling method to estimate the observation frustum and subsequently optimize the object point cloud using multiple temporally continuous observation perspectives.

#### D. Grounding based on DSM

In 3D Visual Grounding task, the user's input query Q is a sentence in natural language, typically consisting of the target

object  $O^T$  and *n* associated objects  $O^A$  that have potential relationships with the target object. When users describe the target object, they often include semantic attributes of the object and implicit semantic relationships between objects, such as "find the transparent glass vase next to the wooden cabinet in the kitchen, with cloud patterns carved on its body."or "help me get a silver bottle opener for opening red wine". However, existing methods struggle to correspond the described information to the objects present in the scene or can only achieve simple alignment. By utilizing DSM, we can extract object attributes and semantic relationships between objects to address this challenge. Therefore, in this section, we propose a grounding method based on DSM, DSM-Grounding, which can enable a deeper level of reasoning and a broader range of perception.

**Candidate Object Extraction Module:** User query Q is often colloquial. To facilitate the extraction of information from the DSM, we extract the target object  $O_q^T$  and potential associated objects  $O_q^R$  from the user's query. To expand the range of objects in the scene for grounding and improving recall, we use  $O_q^T$  and  $O_q^R$  in conjunction with  $O_S$  in the DSM, using fuzzy extraction to obtain the set of candidate targets objects  $O^T$  and the set of candidate relation objects  $O^R$  that help in the query.

Latent Relation Filtering Module: The implicit semantic relationships in the user input query Q can further enhance the filtering process for the candidate objects  $O^T$ , avoiding potential information loss due to excessive filtering. We utilize Q to perform potential semantic filtering on the relationships within the candidate objects, improving the precision of semantic-level filtering. Using  $O^T$  and  $O^R$ , we extract all corresponding  $r_g$  and  $r_s$  from the DSM. To concentrate the filtering information, we structure  $r_g$  and  $r_s$ into the sentence format obtaining r: Between  $O^T$  and  $O^R$ , the spatial relation is  $r_g$  and the semantic relation is  $r_s$ . Then we use the large language model (LLM) to filter the candidate relations R based on the user input and the hierarchy, space or function of all candidate objects  $O^T$  and  $O^R$ , and select the top K potential relation pairs  $R_{topK}$ . Finally, we extract the objects  $O_{topK}$  from the DSM that are associated with  $R_{topK}$ .

(a) Object Level

(b) Place Level

(c) Scene Level

Fig. 4. **Multi Level Rendering.** This illustration shows (a) object, (b) place, and (c) scene levels, providing varying perspectives for detailed analysis and contextual understanding in a 3D environment.

**Multi-Level 3D Grounding**: Based on the list of potential objects  $O_{topK}$  and DSM - G, we render images of objects  $O_{topK}$  in a way similar to SeeGround[18] as shown in Eq.5,

and set the camera on the line connecting the position of the object of potential relationship and the center of the scene as shown in Figure 4. According to the distance between the camera and the potential relationship object, the image I is divided into three level:

- **Object Level**: the object fills the frame, providing detailed insight into its categories and attributes.
- Place Level: with a broader view showing the relationship of objects with adjacent regions.
- Scene Level: the view is expanded to include almost the entire scene for contextual global information.

Then, we extract the corresponding object captions from DSM - S as contextual supplements for the rendered image. These captions, together with the user query Q and the image I, are entered into the Vision-Language Model (VLM) for query reasoning to identify the target object that best matches the specifications in the user query, as in Eq.6.

$$I = \sum_{i=1}^{3} \operatorname{Render}_{i} \left( O_{\operatorname{top} K} \right)$$
(5)

$$pred = VLM(I, O_{topK}, Q)$$
(6)

# E. Implementation Details

In the DSM construction process, we use the openvocabulary detection model YoloWorld[24] for object detection, and a VLM-based image descriptor to extract objects appearing in the images. We use SAM2[25] for segmentation of the detection results. Additionally, we use SigLip[26] and DINOv2 [27] as the text encoder and visual encoder, respectively. During the fusion process, we set the visual threshold  $t_v$  as 0.4 , text threshold  $t_x$  as 0.8, geometric threshold  $t_v$  as 0.3, and total threshold T as 1.5. In DSM-Grounding, we select k = 3 for the top-k relationships. In this paper, all VLMs used are based on OpenAI's GPT-40 (gpt-40-mini).

# IV. EXPERIMENTS

#### A. 3D Semantic Segmentation of DSM-G

We begin by focusing on the map construction and segmentation capabilities, which serve as the foundation for DSM construction. For a comprehensive comparison, we use the Replica [32] dataset as our benchmark. Given that the DSM we constructed differs in labeled tags from those in the actual data, we utilize the following template to form the

| Method        | Unique   |         | Mult     | iple    | Overall  |        |

caption for each object: *This is*  $o_{tag}$ , *its appearance attributes include*  $a_a$ , *its physical attributes are*  $a_p$ , *and its affordance attributes are*  $a_o$ . We then employ LLM to select the most relevant category from the tags in the original dataset, using that category as the semantic label for the point cloud of the object.

In Table III, we present segmentation evaluations based on the model provided by ConceptGraphs[9], comparing our method with existing open-vocabulary 3D semantic segmentation approaches to demonstrate the algorithm's openset segmentation capabilities. The experimental results in Table III indicate that our algorithm consistently outperforms existing methods in segmentation performance.Privileged method is based on fine-tuning for semantic segmentation. Zero-shot method is based on Open vocabulary detection or large models of vision without training for semantic segmentation. We compared the mAcc and F-IoU indicators, which represent the semantic segmentation ability of the method in the entire scene and the segmentation ability of the method for the foreground object. The mAcc of our DSM approach is 38.76, which exceeds most previous algorithms and demonstrates its effectiveness in scene segmentation. The F-mIoU indicator is 67.93, surpassing previous algorithms and highlighting the method's strong segmentation capability for different categories.

## B. DSM-Grounding Experiment on DSM

In order to verify the information recognition ability of DSN-Grounding and the information perception ability of DSM, we applied 10 Ai2thor[33] scenes and 8 Replica[32] scenes to construct DSM and conducted grounding evaluation experiments on the constructed DSM.

**Diverse Query Generation** To ensure the fairness of the evaluation, we proposed a diversified method for generating Grounding evaluation data based on the information in DSM. This method enables the generation of more generalized queries while reducing reliance on the direct content in DSM.We randomly selected an object from DSM and recalled all objects associated with it, along with the relation-

ships between them. Then, we set three normally distributed random values to control the information input of  $a_a$ ,  $a_p$ , and  $a_o$  in their Captions, as shown in Equation 7 and 8. For each generated scene, we constructed 10 unique-type queries and 30 multiple-type queries. We performed caption analysis and word frequency analysis on these, the generated queries shows the characteristics of diverse description types and objects, as shown in Figure 5.

$$X_{i} = N(\mu_{a}, \sigma_{a}) \cdot a_{a} + N(\mu_{p}, \sigma_{p}) \cdot a_{p} + N(\mu_{o}, \sigma_{o}) \cdot a_{o}$$
(7)

$$Query = \{(o_t + X_i, o_r^i + X_i, r^i) \mid o_r^i \in o_r(o_t)\}$$
(8)

Fig. 5. Wordcloud of Queries.

**Result on DSM** We conducted grounding evaluation using the generated queries in the corresponding scenarios, as summarized in Table IV and Table V. For existing zeroshot methods, we compared our approach with state-of-theart algorithms, specifically ZSVG3D [31] and SeeGround [18]. Both of these algorithms are based on LLM and utilize zero-shot open-vocabulary method. For all models tested that utilized parts of VLM, we performed experiments using GPT40 (GPT40-mini).

In terms of overall performance, DSM-Grounding achieved an Acc@0.25 of 60.67 and an Acc@0.5 of 54.28

on the Replica dataset, and an Acc@0.25 of 61.59 and an Acc@0.5 of 60.00 on the Ai2thor dataset, both outperforming existing state-of-the-art methods. These results effectively demonstrate that our method shows superior performance compared to previous algorithms in this task, confirming the effectiveness of our approach.

For unique queries, DSM-Grounding achieved an Acc@0.25 of 78.75 and an Acc@0.5 of 78.75 on the Replica dataset, and an Acc@0.25 of 98.67 and an Acc@0.5 of 98.32 on the Ai2thor dataset, showing a certain improvement compared to the current state-of-theart methods, demonstrating the strong capability of our method in single-object scenarios. For multiple queries, DSM-Grounding achieved an Acc@0.25 of 55.83 and an Acc@0.5 of 47.50 on the Replica dataset, and an Acc@0.25 of 48.70 and an Acc@0.5 of 46.67, both higher than the existing state-of-the-art methods. In both datasets, these metrics are higher than those of existing state-of-the-art methods, indicating a notable improvement. This proves that our method performs well in distinguishing between multiple objects, effectively differentiating between various object categories in the scene using semantic information.

## C. Ablation Study

We conducted ablation studies focusing on three semantic attributes and object relationships, as detailed in Table VI. The Latent Relation Filtering Module (LRF) was evaluated across five experimental groups. In the first group, both the LRF and all three attribute modules were included. The second group omitted the LRF but retained the semantic attributes. The third to fifth groups excluded the LRF and sequentially incorporated only the appearance, physical, and affordance attributes. The results demonstrated that the configuration with all components achieved superior performance, while the subsequent ablated groups showed a progressive decline in success rates. In the ablation study, the first group demonstrated superior performance in both the multiple and general categories, with Acc@0.5 reaching 60.00 and Acc@0.25 achieving 61.59, approximately 10 percent higher than the remaining groups. In the three attribute ablation comparisons, the appearance group showed the highest accuracy, with Acc@0.5 reaching 49.55 and Acc@0.25 reaching 50.45, indicating that VLM has a high dependence on appearance attributes.

# D. Robot Experiment

We conducted experiments in both the self-built simulator and real-world scenarios, as shown in Figure 6. After constructing the DSM in the simulator, we used *the blue book on the table* as the query. Upon finding the target, robot navigation was performed, which was successfully applied to semantic navigation. In the real-world grasping scenario, after constructing the DSM, we used *the red apple next to the white block* as the query. After locating the desired target, robot grasping was performed, which was successfully applied to robotic semantic grasping. These experiments highlight the high-performance retrieval and representation capabilities of our method for scene understanding in robotic systems.

Fig. 6. **Robot Experiment.**(a)Robot Navigation for blue book, (b)Robot Grasping for red apple

# V. LIMITATION

Despite our method performs well in the 3D Visual Grounding task, the DSM-Grounding method has some limitations that require further improvement. The construction of the DSM heavily depends on the quality of the point cloud images and the quality of visual segmentation. A large amount of high-intensity noise can significantly impact the reconstruction results. Additionally, our method is time-consuming, as it relies on the speed at which the visual large model understands the object attributes in the images. In the future, we will consider using representation methods other than point clouds to construct DSM-G, in order to improve the accuracy of scene construction. At the same time, we will attempt to use smaller-computation VLMs and more effective visual prompting methods to achieve faster and more precise semantic information extraction.

#### VI. CONCLUSIONS

In this work, we propose Diverse Semantic Map(DSM), a method for creating a 3D scene representation structure using continuous frames for 3D Viusal Groudning. This significantly enhances robot performance in environmental perception, semantic segmentation, and task execution. Our key innovation lies not only in the construction of a rich semantic map but also in the introduction of grounding tasks based on this map. By integrating comprehensive semantic and relational information into the 3D Visual Grounding task, we substantially improve the retrieval and localization capabilities of multimodal models. Looking ahead, we aim to explore more complex semantic attributes and scene interactions to enhance robot adaptability in dynamic environments.
