# Miscellaneous observations of active galactic nuclei. II. \*

A. C. Gonçalves, P. Véron and M.-P. Véron-Cetty

Observatoire de Haute Provence (CNRS), F-04870 Saint Michel l'Observatoire, France

Received 20 March 1997 / Accepted 22 April 1997

**Abstract.** We observed 37 AGN candidates and classified them on the basis of their spectroscopic properties; three are confirmed QSOs, one is a BL Lac object, nine are Seyfert 1 galaxies, four Seyfert 2s, while twenty are HII regions.

**Key words:** Galaxies: active – Galaxies: nuclei – Galaxies: Seyfert – Galaxies: BL Lacertae objects: general – Galaxies: quasars: general – Galaxies: starburst

### 1. Introduction

In the course of several observing runs, we obtained optical spectra of 37 AGN candidates with uncertain classification. Twenty of them turned out to be extragalactic HII regions ionized by hot stars, while seventeen were confirmed to be QSOs, BL Lac or Seyfert galaxies. In a previous paper (Véron-Cetty & Véron, 1986), the classification of 61 AGN candidates was given.

#### 2. Observations

Most of the observations were carried out in 1995, 1996 and 1997 with the spectrograph CARELEC (Lemaître et al., 1989) attached to the Cassegrain focus of the Observatoire de Haute Provence (OHP) 1.93m telescope. The spectrograph settings used during these runs are given in Table 1. The detector was a  $512 \times 512$  pixels,  $27 \times 27 \mu m$ Tektronic CCD. The slit width was 2.1 arcsec, corresponding to a projected slit width on the detector of  $52 \ \mu m$ , or 1.9 pixel. The resolution, as measured on the night sky emission lines, was 13.5 and 3.4 Å FWHM at low and high resolution, respectively. The spectra were flux calibrated using the standard stars given in Table 1, taken from Oke (1974), Stone (1977), Oke & Gunn (1983) or Massey et al. (1988).

Additional observations were made with EFOSC (Dekker et al., 1988) at the 3.6m ESO telescope in La Silla during two runs in July 1995 and August 1996. The detector was the CCD ESO#26, similar to the one used at OHP. The dispersion was 230 Åmm<sup>-1</sup>; the slit width was 1.5 arcsec, corresponding to 2.2 pixels and resulting in a resolution of 15Å. The wavelength range was  $\lambda\lambda$ 3500-7600 Å. The spectra were flux calibrated using the standard stars W 485A and GD 190 (Oke, 1974).

**Table 2.** Journal of observations. A: OHP, 260 Åmm<sup>-1</sup>; B: OHP, 66 Åmm<sup>-1</sup> blue; C: OHP, 66 Åmm<sup>-1</sup> red; D: ESO, 230 Åmm<sup>-1</sup>. An "\*" after the exposure time indicates the presence of clouds during the exposure.

The journal of observations is given in Table 2 and the list of the observed objects with relevant data, in Table 3. The spectra were analysed in terms of Gaussian components as described in Véron et al. (1997). Table 4 gives for each object the velocity, width and relative strength of each line, together with the adopted classification. Objects with broad Balmer lines were classified as Seyfert 1 galaxies, or QSOs whenever their absolute magnitude was brighter than  $M_B = -23.0$  (assuming  $H_0 =$  $50 \text{ kms}^{-1}\text{Mpc}^{-1}$ ; Seyfert 2s and HII regions were distinguished on the basis of the value of the  $[OIII]\lambda 5007/H\beta$ and  $[NII]\lambda 6584/H\alpha$  line ratios (Veilleux and Osterbrock, 1987). In some cases, the classification is based on a single line ratio, either  $\lambda 5007/H\beta$  or  $\lambda 6584/H\alpha$ . This is potentially dangerous; however we think that in most cases, there is no ambiguity, specially when  $\lambda 6584/H\alpha < 0.3$  (see Fig. 6a in Véron et al., 1997).

## 3. Notes on individual objects

4C 12.05 (Gower et al., 1967) = PKS 0035+121 (Shimmins et al., 1975) has been tentatively identified by Wills & Wills (1976) and Jauncey et al. (1978) with a 16.5-17.0 mag object, the position of which is in good agreement with the accurate radio position measured by Condon et al. (1977); but they have shown that the optical spectrum, although inconclusive, was probably that of a star. How-

ever, Wills & Wills have remarked that there appears to be a small, fainter, south-preceeding blue object, visible on the Palomar Sky Survey prints, blended with the image of the star. A V image, obtained on August 10, 1996 with EFOSC at the 3.6m ESO telescope on La Silla shows that, indeed, the object is double, with a separation of 2.8 arcsec. The spectrograph slit was aligned on the two objects (PA=229°); a 10 min exposure spectrum shows the northfollowing object to be a star, while the south-preceeding object is a QSO at z=1.395 (Fig. 1). The magnitude of the QSO, as measured on the spectrum is about 0.55 mag weaker than the star in B, and 0.87 mag in V. The emission line fluxes are 570 and 360  $10^{-16} \,\mathrm{erg\,s^{-1}\,cm^{-2}}$  for CIII] $\lambda$ 1909 and MgII  $\lambda$ 2798 respectively.

Mark 1147 is an emission line galaxy (Markarian et al., 1980); it has been erroneously classified as a Seyfert 1 by Véron-Cetty & Véron (1985). Our low dispersion spectrum (Fig. 2) shows that it is a HII region, with  $\lambda 5007/H\beta = 2.18$  and  $\lambda 6584/H\alpha = 0.24$ ; this is in agreement with Markarian et al. (1980), who have noticed that  $\lambda 6584$  is weak compared to H $\alpha$ .

Mark 971 = KUG 0101+353 (Takase & Miyauchi-Isobe, 1991b). Markarian et al. (1984) suggested that it could have an active nucleus; this, however, was not confirmed neither by Denisyuk & Lipovetski (1984) nor by Lipovetski et al. (1989). Our spectrum (Fig. 6) shows narrow emission lines ( $< 280 \text{ kms}^{-1} \text{ FWHM}$ ) with  $\lambda 5007/H\beta = 0.41$  together with an H $\beta$  line in absorption; this object is, therefore, a HII region.

Mark 998. According to Markarian et al. (1984), this galaxy could have an active nucleus; Denisyuk & Lipovetski (1984) and Lipovetski et al. (1989) were not able to confirm this. Our low dispersion spectrum (Fig. 2) shows  $\lambda 6584/H\alpha = 0.23$ . It follows that this object is most probably a HII region.

**Q 0155+0220** is an emission line galaxy according to Schneider et al. (1994). Our spectrum (Fig. 6) shows it to be a HII region with narrow (FWHM < 325 kms<sup>-1</sup>) H $\beta$ and  $\lambda$ 5007 emission lines, and  $\lambda$ 5007/H $\beta$  = 0.71.

Mark 596. This object, having  $\lambda 6584/\text{H}\alpha > 1$  may have an active nucleus (Markarian et al., 1984). It is indeed a Seyfert 2 galaxy as our spectrum (Fig. 2) shows that  $\lambda 5007/\text{H}\beta > 5$  and  $\lambda 6584/\text{H}\alpha = 1.14$ .

**KUV 03079-0101** (Noguchi et al., 1980) is an emission line galaxy according to Chaffee et al. (1991). Our spectrum (Fig. 3) shows broad Balmer lines (3000 kms<sup>-1</sup> FHWM) and narrow [OIII] lines. The ratio of the total  $H\beta$  flux to the  $\lambda$ 5007 flux is R=10; this object is therefore a Seyfert 1.0 galaxy (Winkler, 1992).

CBS 74 is a Seyfert galaxy according to Wagner et al. (1988). It was not detected at 4850 MHz by Gregory & Condon (1991) (S < 25 mJy) and is therefore a radioquiet object. Our spectra (Fig. 3, 9) show that it is a Seyfert 1.2 galaxy with a very broad H $\alpha$  component (FWHM ~  $12000 \text{ kms}^{-1}$ ) and R=3.6. Such broad lines are common in radioloud quasars and broad line radiogalaxies (Miley & Miller, 1979; Wills & Browne, 1986; Brotherton et al., 1994; Eracleous & Halpern, 1994), but they are rare in Sevfert galaxies although a few cases are known, such as 2E 0450-1816 (Eracleous & Halpern, 1994) and Arp 102B (Chen & Halpern, 1989). Indeed, powerful radiogalaxies and radioloud quasars with extended radio morphologies tend to have the broadest Balmer lines, while AGNs with compact radiostructure and radioquiet objects have narrower Balmer lines (Miley & Miller, 1979; Steiner, 1981; Wills & Browne, 1986).

HS 0843+2533. The ROSAT X-ray source RX J08469+2522 was identified by Bade et al. (1995) with a 16.8 mag AGN called HS 0843+2533, which exhibits a broad H $\alpha$  emission line (FWHM = 5900 kms<sup>-1</sup>). Our spectrum (Fig. 9) shows, indeed, a strong, broad H $\alpha$  emission line (FWHM = 4850 kms<sup>-1</sup>); this object is therefore a Seyfert 1 galaxy.

Mark 391 = NGC 2691 is a S0a galaxy (Huchra, 1977). For Arakelian et al. (1972), it weakly shows the characteristics of the Seyfert nuclei, with a broad H $\alpha$ emission line (~ 50Å). On this basis, Véron-Cetty & Véron (1985) classified it as a Seyfert 1. Shuder & Osterbrock (1981), however, concluded from their own spectroscopic observations that it is not a Seyfert. Our spectra (Fig. 4) show Balmer lines in absorption together with narrow (FWHM < 215 kms<sup>-1</sup>) emission lines with  $\lambda 5007/H\beta = 1.21$  and  $\lambda 6584/H\alpha = 0.55$ , proving that it is a HII region.

**KUG 0929+324** is a moderate excitation ( $\lambda 5007/\text{H}\beta$  = 2.68) emission line galaxy with an heliocentric radial velocity V = 1500 ± 70 kms<sup>-1</sup> according to Augarde et al. (1994). Our spectrum (Fig. 7) shows that it is a HII region with narrow emission lines (FWHM < 150 kms<sup>-1</sup>) and  $\lambda 6584/\text{H}\alpha = 0.10$ . We found the radial velocity to be V = 4740 kms<sup>-1</sup> (Augarde, 1995, private communication, gave V = 4478 kms<sup>-1</sup>).

CG 49. Salzer et al. (1995) published line intensity ratios for this object as follows:  $\lambda 5007/H\beta = 11.68$  and  $\lambda 6584/H\alpha = 0.30$ . The  $\lambda 6584$  line is too strong for a HII region and too weak for a Seyfert 2 galaxy. Our spectrum shows  $\lambda 6584$  with the same low intensity, however it so happens that the redshifted wavelength of the  $\lambda 6584$ line (6874 Å) falls precisely at the position of the atmospheric B band. When corrected for atmospheric absorption by dividing the observed spectrum by the spectrum of a standard star (Fig. 7), we obtain  $\lambda 6584/H\alpha = 0.79$ , a normal value for a Seyfert 2 galaxy. The measured FWHM of the emission lines is ~ 300 kms<sup>-1</sup>, in agreement with the adopted classification.

**UM 446** is a moderate excitation ( $\lambda$ 5007/H $\beta$  = 4.54) emission line galaxy (Salzer et al., 1989). Our spectrum (Fig. 7) shows narrow emission lines (FWHM < 160 kms<sup>-1</sup>) with  $\lambda$ 6584/H $\alpha$  = 0.04; this object is therefore a HII region.

US 2896 (Huang & Usher, 1984) = CS 109 (Sanduleak & Pesch, 1984) is an emission line galaxy (Mitchell et al., 1984), and a Seyfert 1.5 galaxy according to Everett & Wagner (1995). This is confirmed by our spectrum (Fig. 7) which shows a broad H $\alpha$  component (2100 kms<sup>-1</sup> FWHM). A [OI] $\lambda$ 6300 emission line is observed with  $\lambda$ 6300/H $\alpha$ <sub>narrow</sub> = 0.03.

Mark 646, PG 1203+35 (Green et al., 1986), CG 885 (Pesch & Sanduleak, 1988) or KUG 1203+354 (Takase & Miyauchi-Isobe, 1991a) is a Seyfert galaxy according to Green et al. (1986). Our spectrum (Fig. 7) shows a broad H $\alpha$  component (2350 kms<sup>-1</sup> FWHM); Mark 646 is therefore a Seyfert 1 galaxy. A  $\lambda$ 6300 emission line is observed with  $\lambda$ 6300/H $\alpha$ <sub>narrow</sub> = 0.05.

**2E 1219+0447** is an emission line galaxy (Bothun et al., 1984; Margon et al., 1985). We classify it as a Seyfert 1 galaxy on the basis of a weak, broad (FWHM ~ 8500 kms<sup>-1</sup>) H $\alpha$  component (Fig. 9).

**KUV 13000+2908** (Noguchi et al., 1980), CG 963 (Sanduleak & Pesch, 1990) or PB 3241 (Berger et al., 1991) is a Seyfert 2 galaxy according to Wegner & McMahan (1988). Our spectrum (Fig. 7) shows narrow (FWHM < 185 kms<sup>-1</sup>) emission lines with  $\lambda$ 6584/H $\alpha$  < 0.1, so this object is a HII region.

**Q 1356-067** is a QSO according to Goldschmidt et al. (1992). Our spectrum (Fig. 8), however, shows narrow (FWHM < 280 kms<sup>-1</sup>) emission lines with  $\lambda 6584/\text{H}\alpha =$ 

Fig. 1. Low dispersion spectra (resolution ~ 15 Å) of four objects observed with the 3.6m ESO telescope. The fluxes are in units of  $10^{-16} \text{ erg s}^{-1} \text{ cm}^{-2} \text{\AA}^{-1}$ .

0.16; this object is therefore a HII region. A  $\lambda6300$  emission line is observed with  $\lambda6300/{\rm H}\alpha=0.015$ 

Mark 469, CG 899 (Pesch & Sanduleak, 1989) or KUG 1416+345 (Takase & Miyauchi-Isobe, 1984) is a 16.1 mag, UV excess galaxy (Peterson et al., 1981). Our observations (Fig. 4) show that it is a HII region, with  $\lambda5007/{\rm H}\beta$  = 1.38 and  $\lambda6584/{\rm H}\alpha$  = 0.18, the lines being narrow (FWHM  $<260~{\rm kms^{-1}}).$ 

**PKS 1420-27.** This radiosource was identified by Bolton & Ekers (1966) with an 18 mag QSO. The identification was later confirmed by accurate optical and radio position measurements (Hunstead 1971, 1972). Our spec-

Fig. 2. Low dispersion spectra (resolution ~ 13.5 Å), in the rest frame, of three objects observed with the 1.93m OHP telescope. The fluxes are in units of  $10^{-16} \text{ erg s}^{-1} \text{ cm}^{-2} \text{\AA}^{-1}$ .

trum (Fig. 1) shows that it is indeed a QSO at z = 0.985. The emission line fluxes are 83 and 53  $10^{-16} \,\mathrm{erg}\,\mathrm{s}^{-1}\,\mathrm{cm}^{-2}$  for CIII] $\lambda$ 1909 and MgII  $\lambda$ 2798 respectively.

Mark 816 = KUG 1431+529 (Takase & Miyauchi-Isobe, 1985) is a 16.5 mag, possibly Seyfert, galaxy (Afanasev et al., 1979); however,  $\lambda 6584/\text{H}\alpha < 0.3$  (Afanasev et al., 1980). Our spectrum (Fig. 6) shows narrow emission lines (< 240 kms<sup>-1</sup> FWHM) with  $\lambda 5007/\text{H}\beta = 0.63$ . This object is most probably a HII region.

**PKS 1437-153** is a flat spectrum radiosource identified by Condon et al. (1977) with a 19.0 mag starlike object. It has a featureless spectrum between 3800 and 7000 Å (Fig. 1) and is most probably a BL Lac object.

Mark 833 = CG 590 (Sanduleak & Pesch, 1987) is an emission line galaxy (Markarian et al., 1985) which has been called a "narrow-line active galactic nucleus" by Veilleux & Osterbrock (1987), based on emission-line intensity ratios published by Shuder & Osterbrock (1981); it however happened that the object studied in this last paper is Mark 883 which is, in a few occasions mistakenly called Mark 833 (H. Falcke, private communication). The nature of the emission-line nebulosity in Mark 833 was therefore unknown. Our spectrum (Fig. 8) shows narrow (FWHM < 225 kms<sup>-1</sup>) emission lines with  $\lambda$ 6584/H $\alpha$  = 0.30. This object is, therefore, a HII region.

Mark 483 = CG 741 (Sanduleak & Pesch, 1987) is an emission line galaxy (Markarian et al., 1988; Izotov et al., 1993) with a strong UV excess (U-B = -0.45, Peterson et al., 1981). The emission-line ratios published by Markarian et al. ( $\lambda$ 6584/H $\alpha$  < 0.33) and Izotov et al. ( $\lambda$ 5007/H $\beta$  ~

Fig. 3. Same as in Fig. 2 for three additional objects.

2.0) suggested that it is a HII region. This is confirmed by our spectrum (Fig. 8) which shows narrow emission lines (FWHM < 225 kms<sup>-1</sup>) with  $\lambda 6584/\text{H}\alpha = 0.12$ .

**KUV 15519+2144** is a Seyfert 2 galaxy according to Wagner & Swanson (1990). Our spectrum (Fig. 8) shows it to be a HII region, with narrow (FWHM < 185 kms<sup>-1</sup>) emission lines and  $\lambda 6584/\text{H}\alpha = 0.11$ . A  $\lambda 6300$  emission line is observed with  $\lambda 6300/\text{H}\alpha = 0.02$ 

**Q 1619+3752**, an emission line galaxy according to Schneider et al. (1994), is classified as a HII region, as it shows narrow emission lines (< 240 kms<sup>-1</sup> FWHM) and  $\lambda 5007/\text{H}\beta = 2.56$  (Fig. 6).

**EXO 1622.0+2611.** An AGN for Giommi et al. (1991), this is a Seyfert 1 galaxy, as it presents a broad  $H\alpha$  component (1770 kms<sup>-1</sup> FWHM) (Fig. 8).

**Q 1624+4628**. An emission line galaxy according to Schneider et al. (1994), it is a HII region, with narrow (< 195 kms<sup>-1</sup> FWHM) emission lines and  $\lambda 6584/\text{H}\alpha = 0.40$  (Fig. 8).

**Q** 1638+4634. An emission line galaxy according to Schneider et al. (1994), it is a HII region, with  $\lambda$ 5007/H $\beta$  = 0.86 and  $\lambda$ 6584/H $\alpha$  = 0.40 (Fig. 3).

**Kaz 110**. The emission-line gas in this object was shown to be ionized by hot stars (Kazarian & Tamazian, 1993). Our spectra (Fig. 4) confirm this result, the measured line ratios being:  $\lambda 5007/\text{H}\beta = 2.83$  and  $\lambda 6584/\text{H}\alpha = 0.09$ .

**PKS** 1903-80. This flat spectrum radiosource (Quiniento & Cersosimo, 1993) was identified with a 19.0 mag QSO by Anguita et al. (1979). The identification was confirmed by an accurate radioposition mea-

Fig. 4. Blue and red high dispersion spectra (resolution ~ 3.4 Å), in the rest frame, of three objects observed with the 1.93m OHP telescope. The fluxes are in units of  $10^{-16} \text{ erg s}^{-1} \text{ cm}^{-2} \text{\AA}^{-1}$ .

surement (Russel et al., 1992). It is indeed a QSO at z = 1.756 (Fig. 1). The emission line fluxes are 57 and  $25 \ 10^{-16} \,\mathrm{erg \, s^{-1} \, cm^{-2}}$  for CIV $\lambda 1550$  and CIII] $\lambda 1909$  respectively.

**RN 73** (Ryle & Neville, 1962) = 8C 2037+880 (Rees, 1990) was identified with a 17.5 mag emission line galaxy (Penston, 1971). Our spectra (Fig. 5) show a weak, broad (FWHM ~ 1590 kms<sup>-1</sup>) H $\alpha$  component, but no broad H $\beta$  component: this object is a Seyfert 1.9 galaxy. However, the ratio  $\lambda$ 6584/H $\alpha$ <sub>narrow</sub> = 0.37 is low for a Seyfert galaxy. Halliday (1977) published an accurate radiomap for this source; its position, as measured on this map  $(\alpha_{1950} = 20^{\rm h}36^{\rm m}44^{\rm s}, \, \delta_{1950} = 88^{\circ}01'58'')$ , is about 20 arcsec away from the position of the galaxy, suggesting that the radiostructure and the galaxy are not to be related.

**Q 2233+0123**. An emission line galaxy according to Schneider et al. (1994), it is a Seyfert 1, having a strong and broad (FWHM ~ 5500 kms<sup>-1</sup>) H $\alpha$  component (Fig. 9). The profile of this line deviates significantly from a Gaussian, having a flat top.

Q 2257+0221 is an emission line galaxy according to Schneider et al. (1994). It is a Seyfert 2 having broad

Fig. 5. Same as in Fig. 4 for three additional objects.

(FWHM ~ 500 km s<sup>-1</sup>), asymmetrical [OIII] lines, that are much stronger than H $\beta$  ( $\lambda$ 5007/H $\beta$  ~ 17) (Fig. 6).

NGC 7678 = Kaz 336 (Kazarian & Kazarian, 1980). Although classified as a Seyfert 2 galaxy by Kazarian (1993), this is a HII region with  $\lambda 6584/\text{H}\alpha = 0.52$ ,  $\lambda 5007/\text{H}\beta = 0.25$  and linewidth < 260 kms<sup>-1</sup> FWHM (Fig. 5).

**E 2344+184** is a spiral galaxy (Hutchings & Neff, 1992). According to Margon et al. (1985), it is an emission line galaxy with a strong  $\lambda 6584$  emission line. Our low signal-to-noise blue spectrum (Fig. 6) shows a strong

 $\lambda$ 5007 line ( $\lambda$ 5007/H $\beta > 6$ ), so it is most probably a Seyfert 2 galaxy.

UM 11. Terlevich et al. (1991) gave line ratios:  $\lambda 6584/H\alpha = 1.23$  and  $\lambda 5007/H\beta = 0.83$ , suggesting that this object is a Liner; our spectra (Fig. 5) give  $\lambda 6584/H\alpha = 0.56$  and  $\lambda 5007/H\beta \sim 0.5$  (with linewidth  $< 300 \text{ kms}^{-1}$  FWHM) showing that it is a HII region instead.

Fig. 6. Blue high dispersion spectra (resolution ~ 3.4 Å), in the rest frame, for six objects observed with the 1.93m telescope. The fluxes are in units of  $10^{-16} \text{ erg s}^{-1} \text{ cm}^{-2} \text{\AA}^{-1}$ .

#### 4. Conclusions

We have observed 37 AGN candidates and classified them on the basis of their spectroscopic properties; the line intensities and widths were obtained by fitting the spectra with Gaussian components. We concluded that three of the observed objects are confirmed QSOs, one is a BL Lac object, nine are Seyfert 1 galaxies, four are Seyfert 2s, while twenty are HII regions.

Acknowledgements. We are grateful to Dr. M. Viton for having allowed us to take the low dispersion spec-

trum of CBS 74 during his observing run. This research has made use of the NASA/IPAC extragalactic database (NED) which is operated by the Jet Propulsion Laboratory, Caltech, under contract with the National Aeronautics and Space Administration. A. C. Gonçalves acknowledges support from the JNICT during the course of this work, in the form of a PRAXIS XXI PhD. grant (PRAXIS XXI/BD/5117/95).

**Table 4.** Fitting profile analysis results (see text). Col. 2 gives the redshift used to deredshift the spectra, while col. 3 and 7 give the velocity of the lines as measured on the dereshifted spectra. Col. 6 and 10 give the peak intensity of the H $\beta$  and H $\alpha$  lines respectively (in units of  $10^{-16} \text{ erg s}^{-1} \text{ cm}^{-2} \text{ Å}^{-1}$ ). The FWHM are observed values, not corrected for the instrumental profile; values in parenthesis are from low dispersion spectra and are unresolved.
