Infrared Gluon and Ghost Propagators from Lattice QCD

Results from large asymmetric lattices

Abstract. We report on the infrared limit of the quenched lattice Landau gauge gluon and ghost propagators as well as the strong coupling constant computed from large asymmetric lattices. The infrared lattice propagators are compared with the pure power law solutions from Dyson-Schwinger equations (DSE). For the gluon propagator, the lattice data is compatible with the DSE solution. The preferred measured gluon exponent being ∼ 0 .52, favouring a vanishing propagator at zero momentum. The lattice ghost propagator shows finite volume effects and, for the volumes considered, the propagator does not follow a pure power law. Furthermore, the strong coupling constant is computed and its infrared behaviour investigated.

1 Introduction

In the pure gauge $SU(3)$ Yang-Mills theory, a number of authors has been using first principles approaches, i.e. Dyson-Schwinger equations (DSE) and lattice QCD methods, to investigate the infrared gluon and ghost propagators in Landau gauge, respectively,

$$
D_{\mu\nu}^{ab}(k) = \delta^{ab} \left(\delta_{\mu\nu} - \frac{k_{\mu}k_{\nu}}{k^2} \right) D(k^2), \quad (1)
$$

$$
G_{\mu\nu}^{ab}(k) = -\,\delta^{ab}\,G(k^2)\,,\tag{2}
$$

and the strong coupling constant [\[1\]](#page-2-0) defined as

$$
\alpha_S(k^2) \ = \ \alpha_S(\mu^2) \, Z_{ghost}^2(k^2) \, Z_{gluon}(k^2) \, ; \tag{3}
$$

 $Z_{ghost}(k^2) = k^2 G(k^2)$ and $Z_{gluon}(k^2) = k^2 D(k^2)$ are the ghost and gluon dressing functions. In part, these studies have been trigerred by the solution of the DSE [\[2\]](#page-2-1) which assuming infrared ghost dominance and infrared finiteness of the loop-integrals predicts pure power laws for the dressing functions

$$
Z_{gluon}(k^2) = A (k^2)^{\kappa'}, Z_{ghost}(k^2) = B (k^2)^{-\kappa}. (4)
$$

Moreover, the DSE solution relates the exponents of the two propagators, $\kappa' = 2\kappa$, and predicts a finite strong coupling constant at zero momentum. The infrared solution predicts a vanishing gluon propagator and an infinite ghost propagator at zero momentum ($\kappa > 0.5$). The infrared behaviour of the propagators can be related to gluon confinement criteria [\[3\]](#page-2-2). Looking at this particular

Fig. 1. DSE gluon and ghost dressing functions versus the pure power law solutions. The data is taken from [\[4\]](#page-2-3).

DSE solution for the gluon propagator, the comparison with the pure power law, see figure [1,](#page-0-0) shows that the pure power law is valid only for momenta $k < 200$ MeV. Notice that for the ghost, the deviations from a pure power law start earlier.

One should have in mind that the solution discussed above is a particular solution of the DSE. Indeed, there are, in the literature, different types of solutions for the DSE [\[5\]](#page-2-4). Moreover, the authors of [\[6\]](#page-2-5) have investigated a generalization of the conditions assumed in [\[2\]](#page-2-1) and found alternative behaviours for the infrared gluon and ghost propagators. Given the different scenarios, it would be im-

portant if lattice QCD can provide additional input, helping to check if any of the proposed solutions reproduces the lattice data. For a recent discussion on the infrared behaviour of the gluon and ghost propagators see [\[7\]](#page-2-6).

For the lattice it is a challenge to investigate such low momenta. A possible way out is to consider large asymmetric lattices, which allows to access the momenta required in such an investigation [\[8,](#page-2-7)[9,](#page-2-8)[10,](#page-2-9)[11\]](#page-2-10). Of course, there are lattice effects that have to be carefully estimated. Here we report on the gluon, ghost and strong coupling constant computed from large asymmetric lattices.

2 Gluon Propagator

In [\[11\]](#page-2-10) we have investigated the infrared lattice Landau gauge gluon propagator. For notation and definitions see the above cited article. The simulation uses the Wilson action with $\beta = 6.0$ and combines a number of asymmetric lattices $L^3 \times 256$, $L = 8, 10, 12, 14, 16, 18$ to allow for $L \rightarrow +\infty$ extrapolation. In what concerns the time direction, the $16^3 \times 256$ and $16^3 \times 128$ gluon propagators were compared and no deviations were observed. This suggests that we have a sufficient number of points in the time direction.

For the lattices with the largest time direction, the minimum momentum being accessed is 47 MeV, while for the $16^3 \times 128$ the minimum momentum is 98 MeV. For the largest lattices with $T = 256$ a pure power law in the infrared is observed. In contrast, for the lattice of $16^3 \times$ 128, power law fits are very poor with $\chi^2/d.o.f > 10$. This result is not surprising, given the smallest range of momenta available for this lattice (97 - 294 MeV) and the validity of the pure power law. Nevertheless, the $16³ \times$ 128 will allow us to estimate Gribov copies effects, with reasonable computational effort.

Let us summarize the results reported in [\[11\]](#page-2-10) using the simulations with the largest time extension. Asymmetric lattices display finite size effects (see figures 4 and 5 of [\[11\]](#page-2-10)). However, the extrapolation towards $L \rightarrow +\infty$ is smooth. The extrapolated gluon propagator was well reproduced by a pure power law, with measured $\kappa =$ 0.49 − 0.52. Clearly, the lattice data favors $\kappa \sim 0.52$, in agreement with other theoretical estimates. Unfortunately, one cannot yet provide a definitive answer concerning the value of the gluon propagator at zero momentum. We are currently engaged in trying to give such an answer.

For the $16^3 \times 128$ lattice, Gribov copies effects were estimated by comparing the gluon propagator computed from 164 configurations gauge fixed as in [\[11\]](#page-2-10) (SD in the figures) and the same gauge configurations gauge fixed using the method described in [\[12\]](#page-2-11) (CEASD in the figures), which aims to estimate the absolute maximum of the gauge fixing function. The gluon propagator given by the two methods is, within the statistical precision of the simulation, the same (see figure [2\)](#page-1-0), with the various fits to the lattice data (infrared, ultraviolet, all momenta) reproducing similar results. Therefore, no visible effects of Gribov copies are observed on the gluon propagator.

Fig. 2. Bare gluon propagator for $16^3 \times 128$.

3 Ghost Propagator

The ghost propagator [\[13\]](#page-2-12) was computed using two different methods [\[14,](#page-2-13)[15\]](#page-2-14). The first allows, by solving a linear system, to access all momenta. Its drawback being that, by computing $G(x, 0)$, the statistical errors in the propagator are much larger. The second method requires an inversion of the same linear system per momentum, which is more computationally demanding. However, for the momenta considered, it determines the propagator with better statistical accuracy. Computing the propagator using two methods provides a valuable cross-check.

In the following, for the ghost propagator the colour average was always performed. For the propagator computed with the [\[14\]](#page-2-13) method, in order to reduce the statistical error, seven different sources for the linear system were considered and their result averaged.

For the ghost propagator, one observes sizeable finite size effects (see figure [3\)](#page-2-15), in agreement with the $SU(2)$ study [\[16\]](#page-2-16), and a very sign of clear Gribov copies effects for a large range of momenta.

In what concerns finite volume effects, figure [3](#page-2-15) shows that the ghost dressing function is enhanced when the lattice volume is increased. Moreover, the larger volumes have a larger dressing function and, for the smallest momenta, the derivatives of the dressing function seem to become smaller when the volume increases. The effect of Gribov copies, seen in figure [3,](#page-2-15) cannot be eliminated by the renormalization of the propagator.

To study the compatibility of the ghost propagator with the DSE solutions, the lattice data was fitted to pure power laws and na¨ıve corrections to the pure power law. It turns out that the data are not described by any of the functions considered. Given the results of a similar study for the $16^3 \times 128$ gluon propagator, this result is not a complete surprise.

4 Strong Coupling Constant

The strong coupling constant as defined by equation [\(3\)](#page-0-1) is displayed in figure [4](#page-2-17) for the $16^3 \times 128$ lattice and CEASD gauge fixing method. For the other simulations and the

Fig. 4. Strong coupling constant for $16^3 \times 128$ configurations for the CEASD gauge fixing method; "p2p" ("pws") stands for the ghost computed using [\[14\]](#page-2-13) ([\[15\]](#page-2-14)) method.

SD method, the measured coupling constants are, qualitatively, similar. Figure [5](#page-2-18) show the strong coupling constant for small momenta, for all the simulations considered previously.

The simulations show a decreasing lattice strong coupling constant for small momenta, in agreement with previous lattice calculations [\[17,](#page-2-19)[18\]](#page-2-20). From our simulation, it is not clear if $\alpha_S(0)$ is vanishing. We have tried a number of fits to the strong coupling constant as a function of the momentum, some requiring $\alpha_S(0) = 0$ and some leaving $\alpha_S(0)$ as a free parameter, and the data can be equally described by the two situations. For small momenta, only for the $16³ \times 128$ data and the CEASD gauge fixing algorithm, is α_S described by a pure power law $\alpha_S(q^2) = (q^2)^{\kappa_\alpha}$, with $\kappa_{\alpha} = 0.69$ suggesting a vanishing strong coupling constant at zero momentum. However, notice that the data show that α_S increases with lattice volume as seen in figure [5](#page-2-18) and is affected by Gribov copies. Further studies will hopefully lead to definitive conclusions.
