Abstract

We answer a question due to A. Myasnikov by proving that all expected ranks occur as the ranks of intersections of finitely generated subgroups of free groups.

Mathematics Subject Classification (2000): 20E05

Let F be a free group. Let H and K be nontrivial finitely generated subgroups of F. It is a theorem of Howson [1] that $H \cap K$ has finite rank. H. Neumann proved in [2] that $\operatorname{rank}(H \cap K) - 1 \leq 2(\operatorname{rank}(H) - 1)(\operatorname{rank}(K) - 1)$ and asked whether or not $\operatorname{rank}(H \cap K) - 1 \leq (\operatorname{rank}(H) - 1)(\operatorname{rank}(K) - 1)$.

A. Miasnikov has asked which values between 1 and (m-1)(n-1) can be achieved as rank $(H \cap K) - 1$ for subgroups H and K of ranks m and n—this is problem AUX1 of [4]. We prove that all such numbers occur by proving the following

Theorem. Let F(a, b) be a free group of rank two. Let

$$\begin{split} H^m_{k,\ell} &= \langle a, \ bab^{-1}, \ldots, \ b^k ab^{-k}, \ b^{k+1}a^{n-\ell}b^{-(k+1)}, \\ & b^{k+2}a^n b^{-(k+2)}, \ b^{k+3}a^n b^{-(k+3)}, \ldots, \ b^{m-1}a^n b^{1-m} \rangle \end{split}$$

and let $K = \langle b, aba^{-1}, \ldots, a^{n-1}ba^{1-n} \rangle$, where $0 \leq k \leq m-2$ and $0 \leq \ell \leq n-1$. Then the rank of $H^m_{k,\ell} \cap K$ is $k(n-1) + \ell$.

Corollary. Let F be a free group and let $m, n \ge 2$ be natural numbers. Let N be a natural number such that $1 \le N - 1 \le (m - 1)(n - 1)$. Then there exist subgroups $H, K \le F$, of ranks m and n, such that the rank of $H \cap K$ is N.

Proof of the corollary. The theorem produces the desired subgroups for all N with $N-1 \leq (m-1)(n-1)-1$ after passing to a rank two subgroup of F. For N-1 = (m-1)(n-1), simply let $H = \langle a, bab^{-1}, \ldots, b^{m-2}ab^{2-m}, b^{m-1} \rangle$ and let $K = \langle b, aba^{-1}, \ldots, a^{n-2}ba^{2-n}, a^{n-1} \rangle$.

Proof of the theorem. Let X be a wedge of two circles and base $\pi_1(X)$ at the wedge point. We identify $\pi_1(X)$ with F = F(a, b) by calling the homotopy class of one oriented circle a and the other b. Given a finitely generated subgroup of F,

Figure 1: H, K, and $H \cap K$ when k = m - 2, $\ell = n - 1$

Figure 2: H, K, and $H \cap K$ when k = m - 2, $\ell = n - 2$

there is a covering space \widetilde{X} corresponding to this subgroup. Moreover, there is a compact subgraph of \widetilde{X} that carries the given subgroup. Given two subgroups and their associated finite graphs, one may construct the graph associated to their intersection. These procedures are laid out carefully in [3] and we assume that the reader is familiar with that paper.

In the figures, the graph associated to H appears at the top, that of K to the right, and that of $H \cap K$ in the center. Edges labelled with two arrowheads represent a, those with one arrowhead represent b. Our basepoint in the graph associated to $H \cap K$ is always the vertex in the upperleft corner.

For the moment, fix k = m - 2. In Figure 1, $\ell = n - 1$ and the rank of $H_{m-2,n-1}^m \cap K$ is visibly (m-1)(n-1). Decreasing ℓ by one alters the intersection graph as depicted in Figure 2 and the rank of $H_{m-2,n-2}^m \cap K$ is (m-1)(n-1)-1. Figure 3 shows the case when $\ell = n-3$ and the rank of the intersection is (m-1)(n-1)-2. When $\ell = n-j$, the rank of $H_{m-2,n-j}^m \cap K$ is (m-1)(n-1)-(j-1).

Figure 4 depicts the case $\ell = 0$. Note that the graph associated to $H_{m-2,0}^m \cap K$ is the graph associated to $H_{m-3,n-1}^{m-1} \cap K$ to which a collection of trees have been attached at their roots, the graph associated to $H_{m-3,n-2}^m \cap K$ is the graph

Figure 3: H, K, and $H \cap K$ when k = m - 2, $\ell = n - 3$

Figure 4: H, K, and $H \cap K$ when $k = m - 2, \ell = 0$

associated to $H_{m-3,n-2}^{m-1} \cap K$ to which trees have been so attached, and so on. Since attaching trees in this way leaves the rank intact, we arrive at the theorem by induction on m.
