*Andrzej K. Kwaśniewski***INFORMATION ON COMBINATORIAL INTERPRETATION
OF FIBONOMIAL COEFFICIENTS [LETTER TO THE EDITOR]****Summary**

A combinatorial interpretation of the Fibonomial coefficients is given. (Cf.: binomial Newton and Gaußcoefficients, q -binomial coefficients – ref. [1] and refs. given therein.)

The Fibonacci sequence origin is attributed and referred to the first edition (lost) of “Liber abaci” (1202) by Leonardo Fibonacci [Pisano] (see second edition from 1228 reproduced as *Il Liber Abaci di Leonardo Pisano pubblicato secondo la lezione Codice Magliabeciano* by Baldassarre Boncompagni in *Scritti di Leonardo Pisano* vol. 1, (1857) Rome).

Very recently [1, 2] Fibonomial coefficients [–5] have been given a combinatorial interpretation as counting the number of specific finite “birth-selfsimilar” subposets of an infinite non-tree poset naturally related to the Fibonacci tree of rabbits growth process. (More: in [2] an explicit expression for ζ characteristic function in terms of Kronecker δ of the corresponding incidence algebra was provided- see below for further explanatory links).

In order to supply this combinatorial interpretation we use the following notation: *Fibonomial coefficients* [3–5] are defined as

$$\binom{n}{k}_F = \frac{F_n!}{F_k!F_{n-k}!} \equiv \frac{n_F^k}{k_F!}, \quad n_F \equiv F_n \neq 0,$$

where we make an analogy driven [6, 7] identifications ($n > 0$):

$$n_F! \equiv n_F(n-1)_F(n-2)_F(n-3)_F \dots 2_F 1_F;$$

$$0_F! = 1; \quad n_F^k = n_F(n-1)_F \dots (n-k+1)_F.$$

This is the specification of the notation from [6] for the purpose Fibonomial Calculus case (see Example 2.1 in this Bulletin paper [7]).

Define now a partially ordered infinite set P via its finite part – subposet P_m (rooted at F_1 level subposet) to be continued ad infinitum in an obvious way as seen from the figure of P_5 below. It looks like the Fibonacci tree with a specific “cobweb”.

Fig. 1. Combinatorial interpretation of Fibonomial coefficients.

If one defines this poset P with help of its incidence matrix ζ representing P uniquely then one arrives at ζ with easily recognizable staircase-like structure – of zeros in the upper part of this upper triangle matrix ζ ; see [1,2].

Recall: incidence matrix ζ is defined for any poset as follows ($x, y \in P$):

$$\zeta(x, y) = \begin{cases} 1 & \text{for } x \leq y, \\ 0 & \text{otherwise.} \end{cases}$$

Observation 1

The number of maximal chains starting from the root (level F_1) to reach any point at the n -th level labeled by F_n is equal to $n_F!$.

Observation 2 ($k > 0$)

The number of maximal chains starting from any fixed point at the level labeled by F_k to reach any point at the n -th level labeled by F_n is equal to n_F^m ($n = k + m$).

Observation 3 ($k > 0$)

Let $n = k + m$. The number of subposets P_m rooted at any fixed point at the level

labeled by F_k and ending at the n -th level labeled by F_n is equal to

$$\binom{n}{k}_F \equiv \frac{n_k}{k_F!}.$$

O INTERPRETACJI KOMBINATORYCZNEJ WSPÓŁCZYNNIKÓW DWUMIENNYCH [LIST DO REDAKCJI]

Streszczenie

Przedstawiono poszukiwaną od dziesięcioleci kombinatoryczną interpretację współczynników fibonomialnych. (Porównaj: współczynniki binomialne Newtona czy Gaussa; współczynniki q -binomialne; patrz [1] i referencje tamże.)
