

TRADING STRATEGY ADOPTED OPTIMIZATION OF EUROPEAN CALL OPTION

TOSHIO FUKUMI

ABSTRACT. Optimal pricing of European call option is described by linear stochastic differential equation with mean income and volatility. Trading strategy is given by a twin of stochastic variables for which self-financial condition is not postulated. Optimal pricing will be deformed to be adoptive to trading strategy employing martingale property where stochastic integral w.r.t. analytical solution of Black-Scholes type stochastic differential equation will be employed.

1. STOCHASTIC OPTIMIZATION

1.1. **Black-Scholes Formula.** Black-Scholes' formula starts from heat equation

$$(1.1) \quad \frac{\partial u}{\partial t} = \frac{1}{2} \frac{\partial^2 u^2}{\partial x^2},$$

the solution is given by

$$(1.2) \quad u = \frac{1}{\sqrt{2\pi t}} e^{-\frac{x^2}{2t}},$$

and corresponding stochastic differential equation is

$$(1.3) \quad du_t = dB_t,$$

where B_t denotes Brownian motion. In case there is a drift term we have

$$(1.4) \quad du_t = -cdt + dB_t,$$

whose solution is

$$(1.5) \quad u = \frac{1}{\sqrt{2\pi t}} e^{-\frac{(u-ct)^2}{2t}},$$

where c is a velocity.

Let us modify the last equation to be

$$(1.6) \quad x_t = cdt + \sqrt{\alpha} dB_t,$$

where α is volatility. This equation can be integrated to be

$$(1.7) \quad x_t = \int_0^t c(t-s) \sqrt{\alpha} dB_s.$$

Let

$$(1.8) \quad X_t = X_0 e^{x_t},$$

Key words and phrases. Adoptive optimization, Trading strategy, European call option.

and applying Ito formula we obtain

$$(1.9) \quad dX_t = \mu X_t dt + \sqrt{\alpha} X_t dB_t,$$

where let

$$(1.10) \quad \mu = c + \alpha,$$

which represent averaged income, and this can be integrated to be

$$(1.11) \quad X_t = e^{\sqrt{\alpha} B_t + \frac{(\mu - \alpha)}{2} t}.$$

This is the optimal pricing of European call option known as Black-Scholes formula.¹ It will be worth to note that eq.(1.6) include perturbed drift as a result there is an underlying displacement.

1.2. Trading Strategy. Trading strategy is a twin of stochastic variables denoted by²

$$(1.12) \quad (a_t, b_t).$$

In this equation a_t and b_t are given by as defined in the space of square integral function L^2

$$(1.13) \quad a_t dX_t = \mu X_t dt + \sqrt{\alpha} X_t dB_t$$

and

$$(1.14) \quad db_t = rb_t \beta_t dt,$$

where r denotes interest ratio and β_t is pricing process of bond given by

$$(1.15) \quad d\beta_t = rb_t \beta_t dt.$$

Using these notation the portfolio is given by

$$(1.16) \quad V_t = a_t X_t + b_t \beta_t.$$

1.3. Adaptive Optimization. Let us consider a stochastic integral of optimal pricing w.r.t. trading strategy as follows

$$(1.17) \quad X_t = \int_0^t X_s d\{a_s, b_s\}_s.$$

If r.h.s. does not change pricing is called adoptive to trading strategy. This defines a martingale.³ This means that pricing is globally optimized to trading strategy. This equation can be solved by iteration as follows.

repeat until

$$(1.18) \quad \mathbf{E}(\mathbf{X}_m | \{\mathbf{a}_n, \mathbf{b}_n\}_n) = \mathbf{X}_n < \epsilon, \text{ a.e. } m > n$$

continue

This provides an algorithm implementable into digital computer where the optimal pricing adoptive to trading strategy in which r.h.s denotes a conditional probability. In this case, trading strategy needs not be self-financing.

2. CONCLUDING REMARKS

Optimal pricing for risky asset adoptive to trading strategy was formulated in terms of Ito type stochastic differential equation. It should be noted, however, that there is a limitation in present formulation that it rely on Brownian motion. As a result it depends on Gaussian process based on central limit theorem which states summation of independent variable is governed by Gaussian distribution. The shortcomings arises from the fact that variables are not independent in the real world.
