1. INTRODUCTION

In this article we establish a connection between the Toda lattice defined for a real split semisimple Lie algebra \mathfrak{g} and the integral cohomology of a real flag manifold. We denote by $\check{\mathfrak{g}}$ the real split Lie algebra with Cartan matrix given by the transpose of the Cartan matrix of \mathfrak{g} . Note that $\mathfrak{g} = \check{\mathfrak{g}}$ if \mathfrak{g} is simple and not of type B or C.

The main results establish a "partial dictionary" between objects related to the Toda lattice and objects associated to the flag manifold. Then we have on one side of this dictionary an integrable system, the Toda lattice associated to \mathfrak{g} and related objects, in particular, the set of singularities (blow-up points) of the trajectories of the Toda lattice and the algebraic varieties of the set of zeros of Schur polynomials giving the solutions of the nilpotent Toda lattice. On the other side of the dictionary we have the *real* flag manifold \check{G}/\check{B} of the Lie group \check{G} with $\check{\mathfrak{g}} = \text{Lie}(\check{G})$, \check{B} a Borel subgroup of \check{G} , and other Lie-theoretic objects related to it, such as a maximal compact Lie subgroup \check{K} of \check{G} and the rational cohomology of \check{K} . In this setting of real split semisimple Lie groups, the flag manifold is $\check{G}/\check{B} = \check{K}/\check{T}$ where \check{T} is a *finite* group. Thus $H^*(\check{G}/\check{B}; \mathbb{Q}) = H^*(\check{K}; \mathbb{Q})$ although \check{G}/\check{B} and \check{K} have very different integral cohomology. Therefore one additional object which is connected to the real flag manifold is the cohomology ring $H^*(\check{K}; \mathbb{Q})$. In this paper we then derive certain surprising connections among the Toda lattice, a maximal compact Lie subgroup \check{K} of \check{G} and a finite Chevalley group $\check{K}(\mathbb{F}_q)$ over a field \mathbb{F}_q with q elements. These relations amount to a description

Key words and phrases. Toda lattice, cohomology of compact group, finite Chevalley groups, flag manifold, Painlevé divisor, Frobenius map, Lefschetz fixed point theorem.

of the rational cohomology $H^*(\check{K}; \mathbb{Q})$ in terms of the blow-up points along trajectories of the Toda flow. Moreover this can be refined to give a description of the integral cohomology of \check{G}/\check{B} in terms of the Toda lattice.

It is possible to see the relation between the Toda lattice and the real flag manifold as a generalization of the computation of cohomology of the flag manifold in the complex case. In the complex case the cohomology ring of the flag manifold can be described in terms of polynomials and Weyl group invariant polynomials on a Cartan subalgebra. In the real split case, a split Cartan subgroup H continues to play a central role but now it is regarded as the "isospectral manifold of the Toda flow". To be precise, there is a Toda flow on the connected component of the identity ([15]), and also in (usually) disconnected open dense subsets of the remaining connected components of the Cartan (see [8]). This Toda flow depends, in principle, on a choice $\gamma = (\gamma_1, \ldots, \gamma_l) \in \mathbb{R}^l$ of values for l integrals of motion, i.e. the Chevalley invariants, but its topological structure is independent of the value of γ (if it is generic, i.e. ad-semisimple case with distinct real eigenvalues). This Toda flow gives additional structure to the connected components of H, and this structure will play a role in the cohomology of the real flag manifold. The points in H which are not in the isospectral manifold are blow-up points of the Toda flow. The set of blow-up points is called the Painlevé divisor [11], and it is defined by the zero set of the τ -functions of the Toda lattice, $\mathcal{D}_j := \{\tau_j(t_1, \ldots, t_l) = 0\}$ for each $j = 1, \ldots, l$ where t_k are the flow parameters of the Toda lattice (see below for the details).

We let $\Pi = \{\alpha_1, \ldots, \alpha_l\}$ denote simple roots relative to the Lie algebra \mathfrak{h} of H and we denote the root characters by χ_{α_i} . We can now decompose H into connected components H_{ϵ} where $\epsilon = (\epsilon_1 \dots \epsilon_l)$ with $\epsilon_i \in \{\pm\}$ and $H_{\epsilon} := \{h \in H | \operatorname{sgn}(\chi_{\alpha_i}(h)) = \epsilon_i, i = 1, \ldots, l\}$. It is possible to arrange that there are exactly 2^{l} connected components in the split Cartan subgroup, but for now, this is not necessary. Roughly speaking, the integral cohomology of G/B emerges when one attempts to count the number of connected components in the isospectral manifold of the Toda lattice within one of the connected components of the split Cartan subgroup which we will denote H_{-} , with $H_{-} := H_{\epsilon}$ and $\epsilon = (-\ldots)$. Other connected components of the Cartan subgroup lead to cohomology of G/Bwith local coefficients. From a different point of view, the connected components of the Cartan subgroup are the interior of polytopes, denoted by Γ_{ϵ} , whose vertices correspond to the orbit of the Weyl group. To a first approximation, the graph of incidence numbers of the flag manifold (with edges corresponding to non-zero (co) boundaries on Bruhat cells) is obtained by considering a graph \mathcal{G} where any two Weyl group elements satisfying $w \leq w'$ (Bruhat order) with the lengths, l(w') = l(w) + 1, are connected by an edge if they are in the same connected component of the polytope when blow-up points are removed. The precise definition of the graph \mathcal{G} is in Definition 3.4. We have the following theorem which is restated in a more general form in Theorem 3.6 and then proved in Section 5:

Theorem 1.1. The graph \mathcal{G} defined in terms of the blow-up points of the Toda lattice is also the graph of incidence numbers for the integral cohomology of the real flag manifold $\check{\mathcal{B}} = \check{G}/\check{B}$ in terms of the Bruhat cells.

The connection with cohomology extends to etale cohomology over a field of positive characteristic. If, in the context of the Toda lattice, one attempts to count the number of blow-up points (singularities) along the trajectories of the Toda flow, one ends up obtaining the same numbers that appear in the calculation of Frobenius eigenvalues in the context of the flag manifold (see the example below for the simplest case of this). In more explicit terms, this corresponds to a surprising relation that we find between the multiplicity d of the singularity of the union of the Painlevé divisors, $\mathcal{D}_0 = \bigcup_{j=1}^l \mathcal{D}_j$, at the point p_o of intersection of all the divisors, i.e. $\{p_o\} := \bigcap_{j=1}^l \mathcal{D}_j$, and the polynomial giving the order of a finite Chevalley group $K(\mathbb{F}_q)$. We consider the polynomial in qdefined by $|K(\mathbb{F}_q)|$ (e.g. K = SO(n) for type A). This polynomial has only two non-negative roots, namely q = 1 with multiplicity g and q = 0 with multiplicity r. For example, $|SO(3; \mathbb{F}_q)| = q(q^2-1)$, i.e. g = 1 and r = 1. We define $\tilde{p}(q) := q^{-r}|K(\mathbb{F}_q)|$. Then we obtain that the multiplicity d of this singularity at p_o is given by the formula $d = \deg(\tilde{p}(q))$. This is verified for all type of classical semisimple Lie algebras and type G_2 (Proposition 3.2). This number d also agrees with the total number of blow-ups along the trajectory of the Toda flow (Proposition 6.4). The polynomial $\tilde{p}(q)$ is recovered from the Toda lattice as a polynomial p(q) defined by an alternating sum of the number of blow-up points along trajectories of the Toda lattice (Definition 3.1). It is then shown in Theorem 6.5 that $p(q) = \tilde{p}(q)$. The number d, in the end, has a simple Lie-theoretic description as the dimension of any Borel subalgebra of Lie($K(\mathbb{C})$). This is due to Theorem 9.3.4 of [5]. Then our second main result is summarized as follows (which follows from Theorem 6.5 proved in Section 6.2):

Theorem 1.2. The polynomial $\tilde{p}(q) = q^{-r} |\check{K}(\mathbb{F}_q)|$ given in terms of the order of the finite Chevalley group $\check{K}(\mathbb{F}_q)$ can be recovered in terms of the blow-ups of the Toda lattice, that is, we have $p(q) = \tilde{p}(q)$.

This theorem corresponds to a calculation of the cup product structure in Theorem 1.1 but over the rationals. This is due to the fact that $\tilde{p}(q)$ contains all the information on the cup product structure of the compact group \check{K} .

Let us illustrate our main results by taking the simplest example $\mathfrak{g} = \mathfrak{sl}(2; \mathbb{R})$, which also provides the basic structure of the general case. The $\mathfrak{sl}(2; \mathbb{R})$ -Toda lattice is expressed by the Lax equation,

$$\frac{dL}{dt} = [L, A] = LA - AL,$$

where the 2×2 matrices L and A are given by

$$L = \begin{pmatrix} b_1 & 1\\ a_1 & -b_1 \end{pmatrix}, \qquad B = \begin{pmatrix} 0 & 0\\ a_1 & 0 \end{pmatrix}.$$

The flow of the Toda lattice is expressed by the invariant curve,

$$I(a_1, b_1) = \frac{1}{2} \operatorname{Tr}(L^2) = a_1 + b_1^2 = \text{constant}.$$

Then the isospectral manifold $Z(\gamma)_{\mathbb{R}}$ for a real split case is given by the curve $I(a_1, b_1) = \gamma_1 > 0$ (see Figure 1 where $\gamma_1 = \lambda^2$). The compactified manifold $\tilde{Z}(\gamma)_{\mathbb{R}}$ consists of two polytopes (line segments) Γ_{ϵ} with $\epsilon = \operatorname{sgn}(a_1)$, i.e.

$$\tilde{Z}(\gamma)_{\mathbb{R}} = \Gamma_+ \cup \Gamma_- \cong S^1,$$

where $\Gamma_{\epsilon} = \overline{(\exp(tL^0)B/B)}$ with L^0 the initial matrix of L having $\operatorname{sgn}(a_1^0) = \epsilon$, and B the Borel subgroup of upper triangular matrices. The compactification is obtained by the companion embedding, $Z(\gamma)_{\mathbb{R}} \to G/B$ (see [11, 9]). The Γ_{-} has two connected components of the regular flows which are isolated by the singularity, called the Painlevé divisor marked by \times in the Figure 1. We then define graphs associated with those polytopes Γ_{ϵ} , whose vertices are given by the fixed points, the end-points of Γ_{ϵ} and with an edge \Rightarrow when the vertices are connected by the flow, i.e. no blow-up (see Definition 3.4 for more details). The Γ_+ gives a connected graph with one edge \Rightarrow , and the graph of Γ_- consists of two isolated vertices. We also assign the end-points (vertices) of Γ_{ϵ} with the elements e and s_1 of the Weyl group $W = S_2$, the symmetry group of order two, that is, the vertices are given by the orbit of the Weyl group (recall that the Toda flow defines a torus action on the flag manifold, and the compactified manifold $\tilde{Z}(\gamma)_{\mathbb{R}}$ is a smooth toric variety [8]). In particular, the graph of Γ_- is the same as the incidence graph for the real flag manifold $SL(2; \mathbb{R})/B \cong S^1$, where the edge has the incidence number 2 originally proved in [7] (this is stated as Theorem 3.6 which uses Theorem 4.9).

We now explain the connection between the blow-up of the Toda lattice and the cohomology of a compact Lie group $(SO(2) \cong S^1$ in this case). Let us first consider the complexification $\mathbb{C}^* = \mathbb{C} \setminus \{0\}$ of this flag manifold; and then its reduction to positive characteristic $k_q^* = k_q \setminus \{0\}$ where k_q is an algebraic closure of the finite field \mathbb{F}_q and q is a power of a prime. Consider then the set of \mathbb{F}_q points on this flag manifold. This is the number of elements in $\mathbb{F}_q \setminus \{0\}$, namely q - 1. Similarly, we can just consider the number of elements $|S^1(\mathbb{F}_q)|$, that is, pairs $(x, y) \in \mathbb{F}_q \times \mathbb{F}_q$ satisfying the equation $x^2 + y^2 = 1$. The number $|S^1(\mathbb{F}_q)|$ gives a polynomial in q which can also be obtained cohomologically by considering the Frobenius map, $Fr_q : k_q^* \to k_q^*$, $z \mapsto z^q$ whose Lefschetz number (alternating sum of the traces of Fr_q in (etale) cohomology with proper supports) is given by

$$L(Fr_q) = q - 1.$$

FIGURE 1. The Γ_{ϵ} -polytopes for the A_1 -Toda lattice. The left figure shows the invariant curve $I_1 = a_1 + b_1^2 = \lambda^2$, and the mark \times indicates the blow-up point, the Painlevé divisor. The right figure shows the graphs of Γ_{\pm} -polytopes with the Weyl action. This shows that Γ_{\pm} is connected, and Γ_{-} has two connected components separated by the Painlevé divisor. The numbers in the graph of Γ_{-} indicate $\eta(w)$, i.e. $\eta(e) = 0$ and $\eta(s_1) = 1$.

A characteristic zero analogue of this positive characteristic construction can be given in this simple case. We consider the map: $\Phi_q: S^1 \to S^1, z \mapsto z^q$, a map of degree q. Then we have

$$\begin{cases} H_0(S^1; \mathbb{Q}) = \mathbb{Q} & : q^0 \\ H_1(S^1; \mathbb{Q}) = \mathbb{Q} & : q^1 \end{cases}$$

and now the number of fixed points is q - 1, i.e. the number of non-zero roots of $z^q = z$, or as in the Lefschetz fixed point theorem,

$$L(\Phi_q) = \text{Tr}\left((\Phi_q)_*|_{H_1(S^1;\mathbb{Q})}\right) - \text{Tr}\left((\Phi_q)_*|_{H_0(S^1;\mathbb{Q})}\right) = q - 1$$

We now obtain this polynomial, given as a Lefschetz number, in terms of the singularities of the A_1 Toda flow. Assign to each vertex w in the graph of Γ_- the number of singularities (blow-ups) counted along the flow starting from the top vertex e to the vertex w: We denote the number by $\eta(w)$, so that $\eta(e) = 0$. This polynomial is introduced in Definition 3.1 as

$$p(q) := -\sum_{w \in S_2} (-1)^{l(w)} q^{\eta(w)} = -((-1)q^{\eta(s_1)} + q^{\eta(e)}) = q - 1,$$

which agrees with $L(Fr_q)$, that is, we have (Theorem 6.5)

$$p(q) = L(Fr_q).$$

If q is a power of an odd prime such that $x^2 + 1$ factors over \mathbb{F}_q , this polynomial also gives the number of \mathbb{F}_q points on $SO(2) \cong S^1$, i.e.

$$|S^1(\mathbb{F}_q)| = q - 1.$$

This can be directly computed from the stereographic projection of the circle. Namely with $x = 2s/(s^2 + 1)$, $y = (s^2 - 1)/(s^2 + 1)$, then count the number of solutions $s \in \mathbb{F}_q$ for $x^2 + y^2 = 1$. If $s^2 + 1 = 0$ factors over \mathbb{F}_q then there are q - 2 values of s that give rise to x, y in these formulas plus the point (0, 1). This gives a total of q - 1 points. Also note that the compact group $S^1 \cong SO(2)$ is the maximal compact subgroup of $G = SL(2; \mathbb{R})$ (Theorem 6.5). The main purpose of the present paper is to clarify the correspondence among those objects for the general case of \mathfrak{g} -Toda lattice with real split semisimple Lie algebra \mathfrak{g} .

We also mention some analytic structure of the Toda lattice in the connection of the blow-up with the degree of polynomial p(q): The solution (a_1, b_1) can be expressed by the τ -function (see (2.6) and (2.7) for the details),

$$a_1(t) = \frac{\pm 1}{\tau_1(t)^2}, \quad b_1(t) = \frac{d}{dt} \ln \tau_1(t).$$

The τ -function, $\tau_1(t)$, is given as follows: For the case $a_1 > 0$ (i.e. Γ_+ -polytope), the function τ_1 can be calculated by the companion matrix C_{γ} of L with $\gamma = \lambda^2$ for $a_1^0 = 1$,

$$\tau_1(t_1) = \langle \exp(tC_\gamma)e_1, e_1 \rangle = \cosh(\lambda t_1),$$

where $C_{\gamma} = \begin{pmatrix} 0 & 1 \\ \lambda^2 & 0 \end{pmatrix}$ and $e_1 = (0, 1)^T$ (see (2.7) and also [10]). Since there is no blow-up in this case, there is an edge between the vertices in the graph of Γ_+ (see Figure 1). For the case $a_1 < 0$ (i.e. Γ_- -polytope), we have

$$\tau_1(t_1) = \langle \exp(tC_\gamma)e_2, e_1 \rangle = \frac{1}{\lambda}\sinh(\lambda t_1),$$

where $e_2 = (0, 1)^T$. Thus the solution $(a_1(t), b_1(t))$ blows up at $t_1 = 0$. Near $t_1 = 0$, the τ_1 -function has the form, $\tau_1 = t_1 + \ldots$, in which the first term is the Schur polynomial $S_{(1)}(t_1)$ (see (2.8) for the A_l -Toda lattice). The number of zeros in the τ -functions gives the total number of blow-ups in the Toda flow from the top vertex to the bottom one. In the case of $\mathfrak{sl}(2; \mathbb{R})$ -Toda lattice, this number equals to one which agrees with the degree of polynomial p(q) = q - 1. The agreement that the total number of blow-ups in the Toda flow is equal to the degree of the polynomial p(q) for corresponding Chevalley group $K(\mathbb{F}_q)$ is true for the general case. In Proposition 6.4, we give the explicit numbers for the general case. We also show in Proposition 3.2 that in all types of \mathfrak{g} except E and F the degree of the polynomial p(q) is given by the sum of the minimum degrees in the τ -functions near the point $\{p_o\} = \bigcap_{j=1}^l \mathcal{D}_j$. We then conjecture that the degree is also equal to the number of *real* roots of the product of τ -functions (Conjecture 3.3). The number of the complex roots has been found to be the height $|2\rho|$ where ρ is the sum of all the fundamental weights ([1, 11]).

The numbers $\eta(w)$ of blow-ups along the Toda flow are introduced in Definition 2.10, and the maximum number is obtained by $\eta(w_*)$ with the longest element w_* . Our third main result is the following (Propositions 3.2 and 6.4):

Theorem 1.3. We have $\eta(w_*) = \deg(\tilde{p}(q))$, the dimension of any Borel subalgebra of $\operatorname{Lie}(\check{K}(\mathbb{C}))$. Assuming that the Lie algebra \mathfrak{g} has no factor of type E or F, then we have $\eta(w_*) = d$, where d is the multiplicity of the signarity of $\mathcal{D}_0 = \cup_{j=1}^l \mathcal{D}_j$ at the point p_o of the intersection of all the Painlevé divisors $\mathcal{D}_j = \{\tau_j(t_1, \ldots, t_l) = 0\}$.

Finally we remark that in the simple example of $SL(2; \mathbb{R})$, the connection with cohomology and representation theory of the group can be seen directly. We consider the de Rham chain complex on $G/B \cong K/T \cong S^1$. Let $F(S^1)$ and $\Omega(S^1)$ be the \mathbb{C} -valued functions and 1-forms on G/B with a finite Fourier expansion on S^1 . The cohomology of S^1 appears from the chain complex $M := F^{even}(S^1) \to \Omega^{even}(S^1) =: \tilde{M}$ involving only even powers of $e^{\sqrt{-1}\theta}$. Following the general arguments in [7], this is a map of $\mathfrak{sl}(2; \mathbb{R})$ -modules and the two modules are principal series representations. Note that $F^{even}(S^1)$ consists of functions on $G/B \cong K/T$ and contains constant functions as a trivial \mathfrak{g} -submodule and $\Omega^{even}(S^1)$ which consists of 1-forms only contains the trivial \mathfrak{g} -module as a quotient. The structure of these modules can be described explicitly as well as the map in the chain complex. There are three irreducible modules C, D_+, D_- . The module C is one dimensional and corresponds to the constant functions; each of D_{\pm} is a discrete series representation. The modules D_{\pm} consist of functions involving linear combinations of $e^{n\theta\sqrt{-1}}$ with $\operatorname{sgn}(n) = \pm$. We use labels $q^{i/2}$ to distinguish submodules from quotients, on which the map of \mathfrak{g} -modules (coboundary) sends the quotient $D_+ \oplus D_-$ of M to the submodule $D_+ \oplus D_-$ of \tilde{M} :

Note here that we have normalized the labels in \tilde{M} , so that $D_+ \oplus D_-$, which is in the image of the map, carries the same label in both modules. This map has q^0C in the kernel and q^1C as cokernel giving the cohomology of the circle: $H^*(S^1; \mathbb{C}) = \Lambda(q^1x_1)$, i.e. $H^0(S^1; \mathbb{C}) = C$ (with label q^0) and

 $H^1(S^1; \mathbb{C}) = C$ (with label q^1). This corresponds to the polytope Γ_- and the graph with no edges between e and s_1 (Theorem 3.6).

The filtration described (e.g. $C \subset M$ and $D_+ \oplus D_- \subset \tilde{M}$) is an example of a weight filtration and arises from a filtration via Frobenius eigenvalues (see [6] for a description of these filtration of principal series modules). The labels q^i attached to the cohomology are Frobenius eigenvalues which appear when one considers a field of positive characteristic k, then replace $k \setminus \{0\}$ instead of \mathbb{C}^* , and use etale cohomology with coefficients $\bar{\mathbb{Q}}_m$ for appropriate q and m. The relation to the order of the finite group $|SO(2; \mathbb{F}_q)| = q - 1$ follows by considering the alternating sums of the trace of Frobenius in etale cohomology with proper supports.

There is another chain complex $F^{odd}(S^1) \to \Omega^{odd}(S^1)$ which computes cohomology of $G/B \cong S^1$ with twisted coefficients. The coboundary here is an isomorphism, and therefore the rational cohomology with twisted coefficients is zero. This corresponds to the Γ_+ polytope and the graph $e \Rightarrow s_1$. The edge \Rightarrow represents a coboundary and $H^*(S^1; \mathcal{L}) = 0$ for appropriate twisted coefficients \mathcal{L} .

2. Preliminaries and notations

We now introduce some of the main objects needed to state our main resuls. We will use standard Lie group notation: B, B^* are a pair of opposite Borel subgroups in a split semisimple Lie group $G, B = HN, B^* = HN^*, H$ a split Cartan subgroup, W the Weyl group. The Lie algebras corresponding to those are denoted as $\mathfrak{b} = \mathfrak{h} \oplus \mathfrak{n}$ and $\mathfrak{b}^* = \mathfrak{h} \oplus \mathfrak{n}^*$. The group G is more carefully defined below.

2.1. The real flag manifold and the group G. Let \mathfrak{g} be real split semisimple Lie algebra, $\mathfrak{g}_{\mathbb{C}}$ its complexification. We now consider any complex connected Lie group $G(\mathbb{C})$ with Lie algebra $\mathfrak{g}_{\mathbb{C}}$. The real Lie subalgebra \mathfrak{g} corresponds uniquely to a connected Lie subgroup G.

We can now regard $G(\mathbb{C})$ as an algebraic group and consider the group of real points $G(\mathbb{R})$ containing G as a connected component. We have an algebraic group defined over a finite extension of \mathbb{Q} . For any field k, we denote by G(k) the set of k points. This immediately makes sense when $k = \mathbb{C}$ or \mathbb{R} , but as is pointed out below, by reducing to positive characteristic, we can also make sense of G(k) when k has characteristic of a prime p.

We recall that $\check{\mathfrak{g}}$ the Lie algebra whose Cartan matrix is the transpose of the Lie algebra \mathfrak{g} . The previous construction then will give rise to a connected group \check{G} contained in the simply connected complex group $\check{G}(\mathbb{C})$. We also have flag manifolds $\mathcal{B} = G/B$ and $\check{\mathcal{B}} = \check{G}/\check{B}$.

Remark 2.1. Let $G(\mathbb{C})$ be simply connected. Then the group $\operatorname{Ad}(G)$ is what is denoted G in [8]. The group $\tilde{G} = {\operatorname{Ad}(g) \in \operatorname{Ad}(G(\mathbb{C})) | \operatorname{Ad}(g)\mathfrak{g} \subset \mathfrak{g}}$ is introduced in [8] because its split Cartan subgroup $H_{\mathbb{R}}$ with Lie algebra \mathfrak{h} has exactly 2^l connected components (matching the 2^l polytopes arising from the Toda lattice). Then, using the work of Kostant in [15], we showed in [8] that in the regular ad-semisimple case the isospectral manifold of the Toda lattice is embedded as an open dense set in $H_{\mathbb{R}}$. The connected components of $H_{\mathbb{R}}$ can be pictured as the interior of polytopes Γ_{ϵ} with vertices corresponding to the Weyl group W of \mathfrak{g} . For example the four hexagons in the case of A_2 (with blow-ups included) are identifiable with the connected components of the Cartan subgroup in $SL(3; \mathbb{R})$ consisting of diagonal matrices (see also Figure 2).

We let K denote a maximal compact subgroup of G. It is convenient to think of K as the fixed point set of an involution θ (Cartan involution). Hence we consider an algebraic group endowed with an involution θ and K(k) consists of the θ fixed points of G(k).

Example 2.2. We consider $G(\mathbb{C}) = SL(n; \mathbb{C}) = \check{G}(\mathbb{C})$, i.e. the set of all the $n \times n$ complex matrices A satisfying the polynomial equation, $\det(A) = 1$. Then the complex solutions of $\det(A) = 1$ define $G(\mathbb{C})$. The group of real points is, of course, $G(\mathbb{R}) = SL(n; \mathbb{R})$. The involution θ is given by $\theta(A) = A^*$, the inverse of the transpose of A. We then have K = SO(n) as the set of matrices satisfying $\theta(A) = A$.

2.2. Reduction to positive characteristic. We will show how the Toda lattice and the structure of its blow-up points contains the cohomology of the real flag manifold and of the compact group K. It turns out that it also contains some additional structure which is present when the flag manifold is regarded over a field of positive characteristic. We then need to make sense of the main Lie-theoretic objects over a field \mathbb{F}_q with q elements.

Notation 2.3. We denote $k_q = \mathbb{F}_q$ an algebraic closure of the field \mathbb{F}_q with q elements.

The algebraic groups considered above as well as the involutions θ are defined over a finite extension of \mathbb{Q} . Therefore it is possible to reduce to positive characteristic and define an algebraic group defined over a field \mathbb{F}_q with q elements, where q is a power of a prime number $p, p \neq 2$. We then have the group $G(k_q)$. The involution θ gives rise to an involution θ defined over \mathbb{F}_q and this leads to $K(k_q)$, the points in $G(k_q)$ fixed by the involution θ . We also obtain the finite Chevalley groups $G(\mathbb{F}_q)$ and $K(\mathbb{F}_q)$ by considering the subsets of \mathbb{F}_q points. These two finite groups are, respectively, the fixed points of the Frobenius map $Fr : G(k_q) \to G(k_q)$ and $Fr : K(k_q) \to K(k_q)$ which are reviewed in the example below.

Example 2.4. The equation $\det(A) = 1$ has integral coefficients. The integral coefficients make it possible to reduce modulo a prime p. Let q be a power of a prime p and k_q an algebraic closure of \mathbb{F}_q . We may then consider $G(k_q) = SL(n; k_q)$ the solutions in k_q of $\det(A) = 1$. The Frobenius map is given by $Fr((a_{ij})) = (a_{ij}^q)$. By reducing modulo p the involution $\theta(A) = A^*$ we obtain $SO(n; k_q)$ as the set of fixed points and then the finite group $SO(n; \mathbb{F}_q)$. In the simplest example, n = 2 and

$$SO(n; \mathbb{F}_q)$$
 consists of 2×2 matrices $\begin{pmatrix} x & y \\ -y & x \end{pmatrix}$ satisfying $x^2 + y^2 = 1$ with $x, y \in k_q$.

Remark 2.5. The number of points of $SO(n; \mathbb{F}_q)$ can be found in p.75 of [5]. The formula depends on the Witt index, the dimension of a maximal isotropic subspace. For instance over \mathbb{F}_3 the Witt index of $SO(2; \mathbb{F}_3)$ is zero and $|SO(2; \mathbb{F}_3)| = q + 1 = 4$; however over characteristic 5 there is an isotropic vector space since $1^2 + 2^2 = 0$. In this case $|SO(2; \mathbb{F}_5)| = q - 1 = 4$. By extending \mathbb{F}_3 to \mathbb{F}_{3^2} (adding $\sqrt{-1}$) the number of \mathbb{F}_q points becomes q - 1. In general we have $|SO(n + 1; \mathbb{F}_q)| =$ $|SO(n; \mathbb{F}_q)| \times |S^n(\mathbb{F}_q)|$ (with S^n the sphere given by $x_1^2 + \cdots + x_{n+1}^2 = 1$). Hence $|SO(n + 1; \mathbb{F}_q)| =$ $|S^1(\mathbb{F}_q)| \times |S^2(\mathbb{F}_q)| \times \cdots \times |S^n(\mathbb{F}_q)|$. For example $|SO(6; \mathbb{F}_q)| = |SO(5; \mathbb{F}_q)| \times |S^5(\mathbb{F}_q)|$. We have $|SO(5; \mathbb{F}_q)| = q^4(q^2 - 1)(q^4 - 1)$. However we find that for q = 3, $|S^5(\mathbb{F}_q)| = 252 = q^2(q^3 + 1)$ and for q = 5, $|S^5(\mathbb{F}_q)| = 3100 = q^2(q^3 - 1)$. This gives two different formulas for $|SO(6; \mathbb{F}_q)|$. This is because when q = 3 one obtains a group of type 2A_3 while q = 5 gives a group of type A_3 (see [5]). The problem is the same as in the case of $SO(2; \mathbb{F}_q)$ and it disappears by considering q^2 for q = 3.

We illustrate the computation of $|S^n(\mathbb{F}_q)|$ when $\sqrt{-1} \in \mathbb{F}_q$ by doing the case of n = 2. In particular we compute $|SO(3;\mathbb{F}_q)|$: Using the formulas for the stereographic projection; $x = \frac{2u}{1+u^2+v^2}$, $y = \frac{2v}{1+u^2+v^2}$, $z = \frac{u^2+v^2-1}{1+u^2+v^2}$ and $u = \frac{x}{1-z}$, $v = \frac{y}{1-z}$, we have a bijective correspondence between the set $\{(x, y, z) \in \mathbb{F}_q^3 \mid z \neq 1\}$ and $\{(u, v) \mid 1 + u^2 + v^2 \neq 0\}$. Multiplying by $\sqrt{-1} \in \mathbb{F}_q$, this second set also corresponds bijectively to $\{(u, v) \mid u^2 + v^2 = 1\}$. This produces $q^2 - (q-1)$ points. We now must compute the "north pole" points, i.e. all the (x, y, 1) in the sphere. We then have $x^2 + y^2 = 0$ and thus for $y \neq 0$, $x = \pm \sqrt{-1}y$, that is, 2(q-1) points. Adding (0, 0, 1) we obtain a total of 2(q-1)+1=2q-1 "north pole" elements. We obtain a total of $q^2 - (q-1) + 2q - 1 = q^2 + q = q(q+1)$. Thus, for example, $SO(3;\mathbb{F}_q)$ has $|S^1(\mathbb{F}_q)| \times |S^2(\mathbb{F}_q)| = (q-1)q(q+1) = q(q^2-1)$ points.

We now introduce the "complex version of the real flag manifold". Consider the $K(\mathbb{C})$ -orbit \mathcal{O}_o which is the unique open dense orbit in the complex flag manifold $\mathcal{B}_{\mathbb{C}} = G_{\mathbb{C}}/B_{\mathbb{C}}$. This orbit has the homotopy type of $\mathcal{B} = G/B$ and can be regarded as a *complex version* of the real flag manifold \mathcal{B} . This is the object which we actually study, not just over \mathbb{C} but also over a field of positive characteristic. We also consider all the $K(\mathbb{C})$ -equivariant local systems \mathcal{L} over \mathcal{O}_o . These local systems contain the information to compute integral cohomology of the real flag manifold ([7]).

7

Example 2.6. Let G(k) = SL(2;k). We consider the Cartan involution θ given by $\theta(g) = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} g \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$. Therefore K(k) as the set of fixed points of $\theta(g) = g$ consists of the diagonal matrices $\{\text{diag}(z, z^{-1}) | z \in k^*\}$. The choice of K corresponds to considering the subgroup SU(1,1) of $SL(2;\mathbb{C})$ rather than $SL(2;\mathbb{R})$. The flag manifold is $\mathbb{P}^1 = k \cup \{\infty\}$ and the action of K(k) is $g(z) \cdot y = z^2 y$ for $g(z) \in K(k)$ with $z \in k^*$. The K(k)-orbits are k^* , $\{0\}$ and $\{\infty\}$. Hence for $k = \mathbb{C}$, we have $\mathcal{O}_o = \mathbb{C}^*$. This orbit has the homotopy type of the real flag manifold of SU(1,1), namely a circle S^1 . Take $k = k_q$ and note the map given by $Fr(z) = z^q$. The fixed points are the \mathbb{F}_q points. The map Fr then induces multiplication by q on $H^1(k_q \setminus \{0\}; \overline{\mathbb{Q}}_m)$ (etale cohomology).

2.3. The Toda lattice. Here we present the background information on the Toda lattice: The generalized (nonperiodic) Toda lattice equation related to real split semisimple Lie algebra \mathfrak{g} of rank l is defined by the Lax equation, ([3, 15]),

(2.1)
$$\frac{dL}{dt} = [L, A]$$

where L is a Jacobi element of \mathfrak{g} and A is the \mathfrak{n}^* -projection of L, denoted by $\Pi_{\mathfrak{n}^*}L$,

(2.2)
$$\begin{cases} L(t) = \sum_{i=1}^{l} b_i(t) h_{\alpha_i} + \sum_{i=1}^{l} (a_i(t) e_{-\alpha_i} + e_{\alpha_i}) \\ A(t) = \prod_{\mathfrak{n}^*} L = \sum_{i=1}^{l} a_i(t) e_{-\alpha_i} \end{cases}$$

Here $\{h_{\alpha_i}, e_{\pm\alpha_i}\}$ is the Cartan-Chevalley basis of \mathfrak{g} with the simple roots $\Pi = \{\alpha_1, \dots, \alpha_l\}$ which satisfy the relations,

$$[h_{\alpha_i}, h_{\alpha_j}] = 0, \quad [h_{\alpha_i}, e_{\pm \alpha_j}] = \pm C_{j,i} e_{\pm \alpha_j} , \quad [e_{\alpha_i}, e_{-\alpha_j}] = \delta_{i,j} h_{\alpha_j},$$

where $(C_{i,j})$ is the $l \times l$ Cartan matrix of \mathfrak{g} . The Lax equation (2.1) then gives

(2.3)
$$\begin{cases} \frac{db_i}{dt} = a_i, \\ \frac{da_i}{dt} = -\left(\sum_{j=1}^l C_{i,j}b_j\right)a_i. \end{cases}$$

The integrability of the system can be shown by the existence of the Chevalley invariants, $\{I_k(L) | k = 1, \dots, l\}$, which are given by the weighted homogeneous polynomial of $\{(a_i, b_i) | i = 1, \dots, l\}$ with deg $(a_i) = 2$ and deg $(b_i) = 1$. Those invariant polynomials also define the commutative equations of the Toda equation (2.1),

(2.4)
$$\frac{\partial L}{\partial t_k} = [L, \Pi_{\mathfrak{n}^*} \nabla I_k(L)] \quad \text{for} \quad k = 1, \cdots, l \,,$$

where ∇ is the gradient with respect to the Killing form, i.e. for any $x \in \mathfrak{g}$, $dI_k(L)(x) = K(\nabla I_k(L), x)$. For example, in the case of $\mathfrak{g} = \mathfrak{sl}(l+1, \mathbb{R})$, the invariants $I_k(L)$ with $\deg(I_k) = k+1$ and the gradients $\nabla I_k(L)$ are given by

$$I_k(L) = \frac{1}{k+1} \operatorname{Tr}(L^{k+1})$$
 and $\nabla I_k(L) = L^k$.

The set of commutative equations is called the Toda lattice hierarchy. Note that (2.3) is the first member of the hierarchy, i.e. $t = t_1$. Then the *real* isospectral manifold is defined by

$$Z(\gamma)_{\mathbb{R}} = \left\{ (a_1, \cdots, a_l, b_1, \cdots, b_l) \in \mathbb{R}^{2l} \mid I_k(L) = \gamma_k \in \mathbb{R}, \ k = 1, \cdots, l \right\} = \bigcap_{k=1}^l I_k^{-1}(\gamma_k).$$

The manifold $Z(\gamma)_{\mathbb{R}}$ can be compactified by adding the set of points corresponding to the singularities (*blow-ups*) of the solution. The compactification is obtained through the companion embedding,

 $Z(\gamma)_{\mathbb{R}} \to G/B$ (see [11, 9]). Then the compact manifold $\tilde{Z}(\gamma)_{\mathbb{R}}$ is described by a union of convex polytopes Γ_{ϵ} with $\epsilon = (\epsilon_1, \cdots, \epsilon_l), \ \epsilon_i = \operatorname{sgn}(a_i)$ [8],

$$\tilde{Z}(\gamma)_{\mathbb{R}} = \bigcup_{\epsilon \in \{\pm\}^l} \Gamma_{\epsilon}.$$

Each polytope Γ_{ϵ} is expressed as the closure of the orbit of a Cartan subgroup in the flag manifold, i.e.

$$\Gamma_{\epsilon} = (G^{L^0}B/B), \text{ with } \epsilon = (\epsilon_1 \dots \epsilon_l), \epsilon_i = \operatorname{sgn}(a_i^0),$$

where L^0 is an initial matrix of L(t), and the Cartan subgroup is given by the orbit,

$$G^{L^0} := \left\{ \exp\left(\sum_{k=1}^l t_k \nabla I_k(L^0)\right) \mid t_k \in \mathbb{R}, \ k = 1, \dots, l \right\}.$$

In particular, the polytope $\Gamma_{-\dots-}$, denoted simply as Γ_{-} , is given by

(2.5)
$$\Gamma_{-} = \overline{\left(G^{C_{\gamma}} w_* B/B\right)},$$

where C_{γ} is the companion matrix of L and w_* is the longest element of the Weyl group W. All Γ_{ϵ} are the same polytope with the vertices given by the orbit of Weyl group (see [2]). Each Γ_{ϵ} has a unique intersection with the Painlevé divisors (see below and [9]). Thus in an ad-semisimple case with distinct real eigenvalues, the compact manifold $\tilde{Z}(\gamma)_{\mathbb{R}}$ is a toric variety, and the vertices of each polytope are labeled by the elements of the Weyl group (see Figures below for the examples of Γ_{ϵ} for types A_1, A_2 and G_2).

2.3.1. The τ -functions and Painlevé divisors. The solution of the Toda lattice is obtained by the τ -functions, which are defined by

(2.6)
$$b_k = \frac{d}{dt} \ln \tau_k, \qquad a_k = a_k^0 \prod_{j=1}^l (\tau_j)^{-C_{k,j}},$$

where a_k^0 are some constants (those are obtained from (2.3)). The τ -functions are given by [11]

(2.7)
$$\tau_j(t_1,\ldots,t_l) = \langle g(t_1,\ldots,t_l) \cdot v^{\omega_j}, v^{\omega_j} \rangle, \quad g \in G^{L^0}$$

Here v^{ω_j} is the highest weight vector in the fundamental representation of G, and $\langle \cdot, \cdot \rangle$ is a pairing on the representation space. The blow-up points are given by the zeros of the τ -functions, $\tau_j(t_1, \ldots, t_l) = 0$ for some $j \in \{1, \ldots, l\}$. We then define the Painlevé divisors as the sets of zeros of τ -functions:

Definition 2.7. ([8]) The Painlevé divisor \mathcal{D}_J for a subset $J \subset \{1, \ldots, l\}$ is defined by

$$\mathcal{D}_J := \bigcap_{j \in J} \mathcal{D}_j \quad \text{with} \quad \mathcal{D}_j := \left\{ \left(t_1, \dots, t_l \right) \, | \, \tau_j(t_1, \dots, t_l) = 0 \right\}.$$

The \mathcal{D}_J can be also described by the intersection with the Bruhat cell $N^* w_J B/B$ with the longest element w_J of the Weyl subgroup $W_J = \langle s_j | j \in J \rangle$ ([11, 1]). In particular, the divisor $\mathcal{D}_{\{1,...,l\}}$ is a unique point, denoted as p_o , in the variety $\tilde{Z}(\gamma)_{\mathbb{R}}$, and it is contained in the Γ_- -polytope (see [10]).

In the case of A_l -Toda lattice, one can express the geometric structure of the divisor $\mathcal{D}_0 := \bigcup_{j=1}^l \mathcal{D}_j$ as an algebraic variety near this point p_o (other cases including B_l and C_l are also discussed in [10]): Setting this point as $t = (0, \ldots, 0) \in \mathbb{R}^l$, the τ -functions are given by the following expansion around this point (use (2.7) with $v^{\omega_j} = e_1 \wedge \cdots \wedge e_j$ and $\{e_k\}$ the standard basis of \mathbb{R}^l),

(2.8)
$$\tau_k = (-1)^{\frac{k(k-1)}{2}} S_{(l-k+1,\dots,l)}(t_1,\dots,t_l) + (\text{higher degree terms}).$$

where $S_{(i_1,\ldots,i_k)}$ with $1 \leq i_1 < \cdots < i_k \leq l$ is the Schur polynomial defined as the Wronskian determinant with respect to the t_1 -variable,

$$S_{(i_1,\ldots,i_k)} = \operatorname{Wr}(h_{i_1},h_{i_2},\ldots,h_{i_k}) = \left| (h_{i_\alpha-\beta+1})_{1 \le \alpha,\beta,\le k} \right|.$$

Here $h_j(t_1, \ldots, t_l)$ are complete homogeneous symmetric functions defined by

$$\exp\left(\sum_{k=1}^{l} \lambda^k t_k\right) = \sum_{k=0}^{\infty} \lambda^k h_k(t_1, \dots, t_l) \quad \text{with} \quad h_n = 0 \text{ when } n < 0.$$

Explicitly we have (see [17]),

(2.9)
$$h_k(t_1, \cdots, t_k) = \sum_{k_1+2k_2+\cdots+nk_n=k} \frac{t_1^{k_1} t_2^{k_2} \cdots t_n^{k_n}}{k_1! k_2! \cdots k_n!}$$
$$= \frac{t_1^k}{k!} + \frac{t_1^{k-2} t_2}{(k-2)!} + \cdots + t_{k-1} t_1 + t_k.$$

In particular, $S_{(k)} = h_k$. Those Schur polynomials $S_{(l-k+1,...,l)}$ are the τ -functions for the nilpotent Toda lattice for A-type [10], and the Young diagram associated with $S_{(l-k+1,...,l)}$ is the rectangular box with k-stacks of (l-k+1)-horizontal boxes. Then the degree of the τ_k as a polynomial of t_1 is $k \times (l-k+1)$. The sum of those degrees gives the height $|2\rho|$ where ρ represents the sum of all the fundamental weights ω_j [11].

Then the geometry of the divisor $\mathcal{D}_0 = \bigcup_{j=1}^l \mathcal{D}_j$, the union of the Painlevé divisors $\mathcal{D}_j = \{\tau_j = 0\}$ near the point p_o , can be expressed as the product of τ -functions,

(2.10)
$$F(t_1,\ldots,t_l) := \prod_{j=1}^l \tau_j(t_1,\ldots,t_l) = F_d(t_1,\ldots,t_l) + F_{d+1}(t_1,\ldots,t_l) + \cdots,$$

where each $F_k(t_1, \ldots, t_l)$ is a degree k homogeneous polynomial of (t_1, \ldots, t_l) . The algebraic variety $V := \{F_d = 0\}$ defines the *tangent cone* at the point p_o , and the degree d is the *multiplicity* of the singularity of V at p_o . The degree d is also related to the total number of blow-ups along the trajectory of the Toda flow (Definition 3.1). In this article, we compute the number d and express it as the number of \mathbb{F}_q -points of a finite Chevalley group (Proposition 6.4); or equivalently as the dimension of any Borel subalgebra of $\operatorname{Lie}(\check{K}(\mathbb{C}))$ (see [5]).

Example 2.8. For A_l -Toda lattice, counting the *minimal* degree of the Schur polynomial $S_{(l-k+1,...,l)}$ for each τ_k , one can easily find from (2.10) that d = l(l+2)/4 for l even, and $d = (l+1)^2/4$ for l odd. The number d agrees with the total number of blow-ups in this Toda flow ([14], see also Section 3.1). The d also gives the degree of the polynomial $\tilde{p}(q) = q^{-r} |K(\mathbb{F}_q)|$ (see Propositions 3.2 and 6.4). Note in the case of A_l , K = SO(l+1).

2.3.2. Action of the Weyl group on the signs. Here we give an algebraic description of the blow-ups, so that one can compute the number of blow-ups in the Toda flow: The following action of the Weyl group W on signs describes how the signs of the functions a_j for $j = 1, \ldots, l$ change when a_i blows up.

Definition 2.9. (Proposition 3.16 in [8]) For any set of signs $\epsilon = (\epsilon_1 \dots \epsilon_l) \in \{\pm\}^l$, we define *W*-action on the signs as follows: A simple reflection $s_i := s_{\alpha_i} \in W$ acts on the sign ϵ_j by

$$\epsilon_i : \epsilon_j \longmapsto \epsilon_j \epsilon_i^{C_{j,i}}.$$

We also define the relation \Rightarrow between the vertices of the polytope Γ_{ϵ} as follows: if $\epsilon_i = +$ then we write $\epsilon \xrightarrow{s_i} \epsilon'$ where $\epsilon' = s_i \epsilon$. We also write $w \Rightarrow ws_i$ (see Figure 1).

Thus the sign change is defined on the group character χ_{α_i} with $\epsilon_i = \operatorname{sgn}(\chi_{\alpha_i})$ (recall $s_i \cdot \alpha_j = \alpha_j - C_{j,i}\alpha_i$). We here identify the sign ϵ_i as that of a_i , since the functions a_k are given by (2.6) and the τ -functions are given by the fundamental weights ω_j in (2.7), which relate to the equation $\chi_{\alpha_j} = \prod_{k=1}^l (\chi_{\omega_k})^{C_{j,k}}$ (recall $\alpha_j = \sum_{k=1}^l C_{j,k}\omega_k$). Under the action of the Weyl group, not every simple reflection s_i changes the sign ϵ . The following

Under the action of the Weyl group, not every simple reflection s_i changes the sign ϵ . The following is an alternative way to measure the size of w which only takes into account simple reflections that change the sign ϵ , that is, a trajectory of a Toda lattice having a blow-up point. These numbers will later reappear in the context of the computation of certain Frobenius eigenvalues.

FIGURE 2. The four hexagons Γ_{ϵ} associated to the A_2 -Toda lattice. In each Γ_{ϵ} , the Painlevé divisors \mathcal{D}_j are indicated by the solid curves for the blow-ups of a_1 (i.e. $\tau_1 = 0$) and the dashed curves for the blow-up of a_2 (i.e. $\tau_2 = 0$). The boundaries of the hexagons describe the subsystems given by $a_i = 0$ for i = 1, 2. Each hexagon is divided by the Painlevé divisors into connected components, e.g. Γ_{+-}, Γ_{-+} have two, and Γ_{--} has four connected components. The Toda flow in t_1 -variable is shown as the dotted curve starting from the vertex marked by the identity element e, and ending to the vertex by the longest element $w_* = s_1 s_2 s_1$. The numbers in the polytopes indicate $\eta(w, \epsilon)$, the number of blow-ups along the Toda flow. The signs in each connected components in Γ_{ϵ} represent the signs $(\text{sgn}(a_1), \text{sgn}(a_2))$, while ϵ in Γ_{ϵ} denotes the signs of (a_1, a_2) in the connected component including the top vertex e.

Now the following definition gives the number of blow-ups in the Toda orbit from the top vertex e to the vertex labeled by $w \in W$:

Definition 2.10. For a reduced expression $w = s_{j_1} \cdots s_{j_r}$ and $\epsilon \in \{\pm\}^l$, we define the number,

$$\eta(w,\epsilon) := \left| \{ j_k \mid (s_{j_{k-1}} \cdots s_{j_1} \epsilon)_{j_k} = -, k = 1, \dots, r \} \right|,$$

Namely, for the sequence of signs as the orbit given by w-action,

$$\epsilon \to s_{j_1} \epsilon \to s_{j_2} s_{j_1} \epsilon \to \cdots \to w^{-1} \epsilon.$$

 $\eta(w,\epsilon)$ is the number of \rightarrow which are *not* of the form $\stackrel{s_i}{\Longrightarrow}$ as in Definition 2.9. For example, if $\epsilon = (+ \ldots +)$, then $\eta(w,\epsilon) = 0$, $\forall w \in W$. The number $\eta(w_*,\epsilon)$ for the longest element w_* gives the total number of blow-ups along the Toda flow in Γ_{ϵ} -polytope. Whenever $\epsilon = (- \ldots -)$ we will just denote $\eta(w,\epsilon) = \eta(w)$.

Note that each reduced expression of w corresponds to a path following Toda lattice trajectories along 1-dimensional subsystems leading to w. Each 1-dimensional subsystem is equivalent to A_1 -Toda lattice discussed in Introduction. It can be shown that $\eta(w, \epsilon)$ is independent of the reduced expression (Corollary 5.2). Hence the number of blow-up points along trajectories in one-dimensional subsystems in the boundary of the Γ_{ϵ} -polytope is independent of the trajectory (parametrized by a reduced expression).

We will find below a computation of $\eta(w_*)$, the total number of blow-ups along the Toda flow, in terms of the polynomial computing the order of $K(\mathbb{F}_q)$. Alternatively, $q^{-\eta(w_*)}$ is given in terms of the Hecke algebra operators of Lusztig and Vogan in [16] (Remark 4.7 combined with Proposition 5.2). The expression $q^{\eta(w_*)}$ is also the Frobenius eigenvalue occurring in the top (etale) cohomology group of the open dense $K(k_q)$ orbit $\mathcal{O}_o(k_q)$ (Proposition 6.1).

Example 2.11. The cases of A_2 and G_2 are illustrated in Figures 2 and 3. In these figures the four hexagons and 12-gons are shown as the Γ_{ϵ} -polytope with the signs $\epsilon = (\epsilon_1 \epsilon_2)$. These polytopes glue together to form a compact isospectral manifold $\tilde{Z}(\gamma)_{\mathbb{R}} = \bigcup_{\epsilon \in \{\pm\}^2} \Gamma_{\epsilon}$. In [9], we have shown for example that $\tilde{Z}(\gamma)_{\mathbb{R}}$ gives a connected sum of two Klein bottles for A_2 , and a connected sum of five

FIGURE 3. The four 12-gons Γ_{ϵ} associated to the G_2 -Toda lattice. The Painlevé divisors corresponding to the blow ups of a_1 and a_2 are indicated by the solid and dashed curves, respectively. The Toda flow in t_1 -variable is shown as the dotted curve starting from the vertex marked by e, and ending to the vertex by $w_* = s_1 s_2 s_1 s_2 s_1 s_2$. The numbers in Γ_{ϵ} represent $\eta(w, \epsilon)$.

Klein bottles for G_2 . Trajectories of the Toda lattice starts in the vertex associated to e and move towards the vertex corresponding to the longest element w_* in the Weyl group.

In the case of A_2 , the W-action on the signs $\epsilon = (\epsilon_1 \epsilon_2)$ gives $s_1(--) = (-+)$, $s_2(-+) = (-+)$ and $s_1(-+) = (--)$. From those we obtain $\eta(e) = 0$, $\eta(s_1) = \eta(s_2) = \eta(s_1s_2) = \eta(s_2s_1) = 1$ and $\eta(s_1s_2s_1) = 2$. Those give the numbers of blow-ups in the Toda flow (see Figure 2).

In the case of G_2 , we obtain $\eta(e) = 0$, $\eta(s_1) = \eta(s_2) = \eta(s_1s_2) = \eta(s_2s_1) = 1$, $\eta(s_1s_2s_1) = \eta(s_2s_1s_2) = 2$, $\eta(s_1s_2s_1s_2) = \eta(s_2s_1s_2s_1) = \eta(s_1s_2s_1s_2s_1) = \eta(s_2s_1s_2s_1s_2) = 3$ and $\eta(w_*) = 4$. The total number of blow-ups $\eta(w_*)$ is then 4 (see Figure 3).

Before closing this Section, we mention a Poincaré duality relation satisfied by the numbers $\eta(w)$:

Proposition 2.1. The number $\eta(w)$ satisfies the following Poincaré duality relation,

$$\eta(w_*) = \eta(w_*w) + \eta(w) \,.$$

Proof. First note that $w_*(-\ldots -) = (-\ldots -)$. Also we note that w_*w gives a path from w_* to w_*w which is dual to the path from e to w (recall w acts on ϵ as $w^-1\epsilon$). Since $(w_*w)^{-1}(-\ldots -) = w^{-1}(-\ldots -)$, we get $\eta(w_*w) = \eta(w_*) - \eta(w)$. \Box

3. Blow-ups and graph of incidence numbers

The strategy in the proof of our main results of constructing a partial dictionary between the objects in the Toda lattice and the flag manifold has the following order:

- (1) First define the polynomial p(q) in terms of the blow-ups along the trajectory of the Toda flow (Definition 3.1).
- (2) Compute directly the multiplicity d of the singularity of $\mathcal{D}_0 = \bigcup_{j=1}^l \mathcal{D}_j$ of the union of the Painlevé divisors at the point of intersection p_o of the divisors, $\{p_o\} = \bigcap_{j=1}^l \mathcal{D}_j$. Then show d is also given by the degree of the polynomial $\tilde{p}(q) := q^{-r} |K(\mathbb{F}_q)|$, which is the dimension of any Borel subalgebra of $\text{Lie}(K(\mathbb{C}))$ (Proposition 3.2).
- (3) Define the graph \mathcal{G}_{ϵ} associated with the blow-ups in the polytope Γ_{ϵ} (Definition 3.4). The signs $\epsilon_i := \operatorname{sgn}(a_i)$ on Γ_{ϵ} are interpreted in terms of local systems arising in the computation of integral cohomology of the real flag manifold (Definitions 4.3).
- (4) Also define the graph $\mathcal{G}_{\mathcal{L},\mathcal{B}}$ in terms of a locally constant sheaf \mathcal{L} , which leads to $H^*(\mathcal{B};\mathcal{L})$ (Definition 4.4).
- (5) Show that the graphs \mathcal{G}_{ϵ} and $\mathcal{G}_{\mathcal{L},\mathcal{B}}$ coincide (Theorem 3.6 and Proof is given in Section 5). This completes the relation between the integral cohomology of the real flag manifold and the blow-up structure of the Toda lattice.
- (6) Count the number of blow-ups along trajectories of the Toda lattice, and relate it to Frobenius eigenvalues in the flag manifold over positive characteristic (Proposition 6.1).

- (7) Show $H^*(\mathcal{B}; \mathbb{Q}) = H^*(K; \mathbb{Q})$ (Proposition 6.3).
- (8) Apply Lefschetz fixed point theorem to the Frobenius map to derive a relation between the number of blow-up points along trajectories of the Toda lattice and the order of finite Chevalley group $K(\mathbb{F}_q)$ (Theorem 6.5).
- (9) Show that the degree of p(q) gives the multiplicity d of the union of all the Painlevé divisors at the point of intersection p_o , i.e. $d = \eta(w_*)$ (Proposition 6.4).

3.1. The polynomial p(q). We now introduce polynomials in terms of the numbers $\eta(w, \epsilon)$ in Definition, 2.10 which play a fundamental role in this paper. We refer to these polynomials as the *alternating sum of the blow-ups*. For each Γ_{ϵ} -polytope we then define $p_{\epsilon}(q)$:

Definition 3.1. We define a polynomial, the alternating sum of the blow-ups,

(3.1)
$$p_{\epsilon}(q) = (-1)^{l(w_{*})} \sum_{w \in W} (-1)^{l(w)} q^{\eta(w,\epsilon)}$$

where w_* is the longest element of the Weyl group and l(w) indicates the length of w. When $\epsilon = (-\ldots -)$, we simply denote this polynomial by p(q). The degree of p(q) gives the total number of blow-ups along the Toda flow, $\eta(w_*) = \deg(p(q))$.

We then have:

Proposition 3.1. We have $p_{\epsilon}(q) = 0$ unless $\epsilon = (-\ldots -)$.

Proof. If the *i*th component ϵ_i of ϵ is +, then we have $s_i \epsilon = \epsilon$ and hence $\eta(e, \epsilon) = \eta(s_i, \epsilon) = 0$. Now for any $w \in W$ such that $l(s_i w) = l(w) + 1$, we have $\eta(w, \epsilon) = \eta(s_i w, \epsilon)$ (note that $\epsilon = s_i \epsilon$ and applying w^{-1} on both sides we also have $w^{-1}\epsilon = w^{-1}s_i\epsilon = (s_i w)^{-1}\epsilon$). This implies $\eta(w, \epsilon) = \eta(s_i w, \epsilon)$. Then for any w of minimal length in its coset in $\langle s_i \rangle \backslash W$, the sum contains a pair $q^{\eta(w,\epsilon)}$ and $q^{\eta(s_i w,\epsilon)} = q^{\eta(w,\epsilon)}$ of opposite signs, and hence they do not contribute the sum. By writing the sum over W as a sum over the set of disjoint cosets of $\langle s_i \rangle \backslash W$ we obtain $p_{\epsilon}(q) = 0$. \Box

Hence the only relevant polynomial here is p(q), the polynomial for the Γ_{-} -polytope. This proposition corresponds under our dictionary to the fact that the *rational* cohomology of K and $\mathcal{B} = K/T$ actually agree. Recall that we are dealing only with the case when the Lie algebra is split and the group T is then a finite group. The polynomial $p_{\epsilon}(q)$ corresponds, under our dictionary, to a Lefschetz number for the Frobenius action over a field of positive characteristic for cohomology with local coefficients. When q = 1 these polynomials all vanish, including p(q). This reflects the fact that the Euler characteristic of K is zero.

As we will explain below that the numbers $\eta(w, \epsilon)$ are deeply tied up with the cohomology of the flag manifold. The polynomial p(q) under our dictionary, contain all the information regarding the cohomology ring of the compact Lie group K.

Example 3.2. From Figures 2 and 3, we note that the numbers $\eta(w, \epsilon)$ are constant on the connected components in a given Γ_{ϵ} -polytope. The polynomials p(q) that are obtained from (3.1) by counting $\eta(w)$ are $p(q) = q^2 - 1$ for type A_2 , and $(q^2 - 1)^2$ for type G_2 . The A_3 example is a bit more complicated but it gives the same polynomial $p(q) = (q^2 - 1)^2$ obtained in the G_2 case (see Figure 5 below). The reason given earlier is that K is in both cases essentially $SU(2) \times SU(2)$. This will become clear when the connection with K is made below.

We are also interested in the degree of the polynomial p(q), i.e. $\eta(w_*)$. One reason for this is the following (see also below Eq. (2.10)):

Conjecture 3.3. The degree $\eta(w_*)$ of the polynomial p(q) is the multiplicity d of the singularity of the divisor given by $\mathcal{D}_0 = \bigcup_{j=1}^l \mathcal{D}_j$ at the point p_o where all the divisors $\mathcal{D}_j = \{\tau_j = 0\}$ intersect. Namely the number d is given by the minimal degree of the product of the τ -functions, i.e. (2.10). Furthermore, the degree $\eta(w_*)$ also gives the number of *real* roots of the Schur polynomials associated to the nilpotent Toda lattices (see [10] for the nilpotent Toda lattices).

The first part of the conjecture can be verified directly for the Toda lattice associated with any Lie algebra of the classical type or type G_2 by counting the minimal degrees of Schur polynomials, which are the leading terms of the τ -functions near the point p_o : First note that the τ -functions for the nilpotent Toda lattices are obtained from (2.7). Then find explicit forms of the highest weight vectors and the companion matrix (the regular nilpotent element) for each algebra. The following is the result based on the nilpotent Toda lattices:

In the case of A_l -Toda lattice, the τ -functions are given by the Schur polynomials in (2.8), i.e.

$$\tau_k(t_1,\ldots,t_l) = (-1)^{\frac{k(k-1)}{2}} S_{(l-k+1,\ldots,l)}(t_1,\ldots,t_l) \quad k = 1,\ldots,l.$$

The minimal degrees of those Schur polynomials are given as follows:

• For l even, the minimal degrees of τ_j , $j = 1, \ldots, l$, are given by

1, 2, ...,
$$\frac{l}{2}$$
, $\frac{l}{2}$, ..., 2, 1,

(e.g. $\tau_1 \sim t_l$, $\tau_2 \sim t_{l-1}^2$ and $\tau_l \sim t_l$). The sum of those degrees then gives $d = \frac{l(l+2)}{4}$. • For l odd, the minimal degrees are

1, 2, ...,
$$\frac{l-1}{2}$$
, $\frac{l+1}{2}$, $\frac{l-1}{2}$, ..., 2, 1.

from which we have $d = \left(\frac{l+1}{2}\right)^2$.

In the case of B_l -Toda lattice, the τ -functions are given by

$$\tau_k(t_1, t_3, \dots, t_{2l-1}) = \operatorname{Wr}(h_{2l}, \dots, h_{2l-k+1}) \quad k = 1, \dots, l-1$$

and

$$\tau_l(t_1, t_2, \dots, t_{2l-1}) = \sqrt{|\operatorname{Wr}(h_{2l}, \dots, h_{l+1})|},$$

where h_k are given in (2.9) with $t_{2k} = 0$ for all even parameters (see [10]). Then we have:

• For *l* even, the minimal degrees are given by

2, 2, 4, 4, ...,
$$l-2$$
, $l-2$, l , $\frac{l}{2}$

(e.g. $\tau_1 \sim t_1 t_{2l-1}$, $\tau_2 \sim t_{2l-1}^2$ and $\tau_l \sim (t_{l+1})^{l/2}$). The degree d is then given by $d = \frac{l(l+1)}{2}$. • For l odd, the minimal degrees are

2, 2, 4, 4, ...,
$$l-1, l-1, \frac{l+1}{2},$$

from which we have $d = \frac{l(l+1)}{2}$.

In the case of C_l -Toda lattice, the τ -functions are

$$\tau_k(t_1, t_3, \dots, t_{2l-1}) = \operatorname{Wr}(h_{2l-1}, \dots, h_{2l-k}) \quad k = 1, \dots, l$$

Again one takes $t_{2k} = 0$ for h_n . Then the minimal degrees are given by

1, 2, 3, ..., l-1, l.

This gives $d = \frac{l(l+1)}{2}$ (which is the same as B_l -case).

In the case of D_l -Toda lattice, the τ -functions are given as follows:

• For l even, they are given by, for $k = 1, \ldots, l - 2$,

$$\tau_k(t_1, t_3, \dots, t_{2l-3}, s) = \operatorname{Wr}(sh_{l-1} + 2h_{2l-2}, sh_{l-2} + 2h_{2l-3}, \dots, sh_{l-k} + 2h_{2l-1-k}).$$

The τ_{l-1} and τ_l are given by

$$[\tau_{l-1} \cdot \tau_l](t_1, t_3, \dots, t_{2l-3}, s) = \operatorname{Wr}(sh_{l-1} + 2h_{2l-2}, \dots, sh_2 + 2h_l),$$

and

$$(\tau_l(t_1, t_3, \dots, t_{2l-3}, s))^2 = \begin{cases} sh_{l-1} + 2h_{2l-2} & sh_{l-2} + 2h_{2l-3} & \cdots & sh_1 + 2h_l & s+h_{l-1} \\ sh_{l-2} + 2h_{2l-3} & sh_{l-3} + 2h_{2l-4} & \cdots & s+2h_{l-1} & h_{l-2} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ sh_1 + 2h_l & s+2h_{l-1} & \cdots & 2h_2 & h_1 \\ s+h_{l-1} & h_{l-2} & \cdots & h_1 & 0 \end{cases}$$

Here the even parameters are all zero $t_{2k} = 0$, and s is a flow parameter associated with the Chevalley invariant with degree l. Counting the minimal degrees of the τ -functions, we have

2, 2, 4, 4, ...,
$$l-2$$
, $l-2$, $\frac{l}{2}$, $\frac{l}{2}$,

(e.g. $\tau_1 \sim st_{l-1}, \ \tau_2 \sim t_{2l-3}^2$ and $\tau_l \sim s^{l/2}$). Then we have $d = \frac{l^2}{2}$. • For l odd, the τ -functions are given by, for $k = 1, \ldots, l-2$,

$$\tau_k(t_1, t_3, \dots, t_{2l-3}, s) = \operatorname{Wr}(s^2 + 2h_{2l-2}, 2h_{2l-3}, \dots, 2h_{2l-1-k})$$

The last two τ -functions are

$$[\tau_{l-1} \cdot \tau_l](t_1, t_3, \dots, t_{2l-3}, s) = \operatorname{Wr}(s^2 + 2h_{2l-2}, 2h_{2l-3}, \dots, 2h_l),$$

and

$$(\tau_l(t_1, t_3, \dots, t_{2l-3}, s))^2 = \begin{vmatrix} s^2 + 2h_{2l-2} & 2h_{2l-3} & \cdots & 2h_l & s+h_{l-1} \\ 2h_{2l-3} & 2h_{2l-4} & \cdots & 2h_{l-1} & h_{l-2} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 2h_l & 2h_{l-1} & \cdots & 2h_2 & h_1 \\ s+h_{l-1} & h_{l-2} & \cdots & h_1 & 1 \end{vmatrix}$$

Now the minimal degrees of the τ -functions are

2, 2, ...,
$$l-3$$
, $l-3$, $l-1$, $\frac{l-1}{2}$, $\frac{l-1}{2}$.

Then we have $d = \frac{l^2 - 1}{2}$.

In the case of G_2 , we have

$$\tau_1(t_1, t_5) = h_6, \quad \tau_2(t_1, t_5) = \operatorname{Wr}(h_6, h_5).$$

Here the parameters are only t_1 and t_5 and all others take zero. The minimal degree is then 2 for each τ -function, i.e. $\tau_1 \sim t_1 t_5$ and $\tau_2 \sim t_5^2$, and we have d = 4.

We can summarize these computations in the following:

Proposition 3.2. Let \mathfrak{g} be a split semisimple Lie algebra not containing factors of type E or F. The multiplicity d of the singularity at p_o , given as the minimal degrees of Schur polynomials in (2.8), is the dimension of any Borel subalgebra of $\operatorname{Lie}(\check{K}(\mathbb{C}))$. Moreover, d is also the degree of the polynomial $\tilde{p}(q) = q^{-r} |\check{K}(\mathbb{F}_q)|$.

Proof. The statement concerning the dimension of any Borel subalgebra follows case-by-case from the explicit computations that are listed above. This relies on an approximation near p_o of the tau functions in the semisimple case by the tau functions in the nilpotent case (given by Schur polynomials). One also needs the list of groups K that appear in each case. This is provided, for example, in the satement of Theorem 6.5. The second statement uses a formula for the sum of the degrees of basic invariant polynomials. This sum gives the degree of the polynomial $\tilde{p}(q) = q^{-r} |\check{K}(\mathbb{F}_q)|$. This formula is Theorem 9.3.4 of [5]. \Box

In Proposition 6.4, those numbers d are shown to be also the degrees $\eta(w_*)$ of p(q). Note that d is the multiplicity of a singularity and $\eta(w_*)$ is defined differently, as the maximal number of blow-ups encountered along the Toda flow, counted along one dimensional subsystems. These polynomials p(q), the alternating sum of the blow-ups, are then shown to agree with the polynomials $\tilde{p}(q)$. Also notice that the minimal degree for each τ -functions is quite similar to each degree d_i of the basic W-invariant polynomial of the Chevalley group K (see [5] or Theorem 6.5 below). We did not compute the exact relation between those degrees, but we expect that each degree d_i is related to the number of real intersection points on the tangent cone $V = \{F_d = 0\}$ defined in (2.10) with a linear line corresponding to the t_1 -flow of the Toda lattice. This may be stated as

$$\deg(p(q)) = \max_{c \in \mathbb{R}^{l-1}} |\{\mathcal{D}_0 \cap L_c \mid \text{transversal intersection}\}|$$

where $\mathcal{D}_0 = \bigcup_{j=1}^l \{\tau_j = 0\}$ and $L_c := \{(t_1, c_2, \dots, c_l) | c = (c_2, \dots, c_l) \in \mathbb{R}^{l-1}\}$. It is interesting to note that the degrees d_i and the minimal degrees of τ -functions are the same for the cases having the same ranks, $l = \operatorname{rank}(\mathfrak{g}) = \operatorname{rank}(K)$, i.e. the cases of B, C and D_l with l even (see Theorem 6.5).

3.2. The graphs associated to the blow-ups. The following graph \mathcal{G}_{ϵ} was originally motivated by the problem of computing the number of connected components in the Γ_{ϵ} -polytope. This problem is analogous to the problem of computing the intersection of two opposite top dimensional Bruhat cells in the case of a real flag manifold (e.g. see [21, 19, 22]). Here we were counting the number of connected components appearing in the intersection $(N^*B/B) \cap (G^{C_{\gamma}}w_*B/B)$ where $G^{C_{\gamma}}$ is defined in (2.5) (note in particular, when $\gamma = 0$ (nilpotent case), $G^{C_0} \subset N$). Also note that the Painlevé divisor $\mathcal{D}_J := \bigcap_{j \in J} \mathcal{D}_j$ for $J \subset \{1, \ldots, l\}$ corresponds to the N^* -orbit, N^*w_JB/B , where w_J is the longest element of the subgroup $W_J := \langle s_i | i \in J \rangle$ (see [11, 9]). We then observed that in all examples this was the graph of incidence numbers for a real flag manifold, observation which then started the present study.

Definition 3.4. For a fixed $\epsilon = (\epsilon_1 \dots \epsilon_l)$, we associate a graph \mathcal{G}_{ϵ} to the blow-ups of the Toda lattice. The graph consists of vertices labeled by the elements of the Weyl group W, i.e. the vertices of the Γ_{ϵ} -polytope, and oriented edges \Rightarrow . The edges are defined as follows: For any $w_1, w_2 \in W$, there exist an edge between w_1 and w_2 ,

$$w_1 \Rightarrow w_2 \quad \text{iff} \quad \begin{cases} a) \ w_1 \leq w_2 \ (\text{Bruhat order}) \\ b) \ l(w_2) = l(w_1) + 1 , \\ c) \ \eta(w_1, \epsilon) = \eta(w_2, \epsilon) , \\ d) \ w_1^{-1} \epsilon = w_2^{-1} \epsilon . \end{cases}$$

When $\epsilon = (-\ldots -)$, we simply denote $\mathcal{G} = \mathcal{G}_{\epsilon}$.

Note that if there exists a path from w_1 -vertex to w_2 -vertex without crossing a Painlevé divisor (i.e. no blow-up), then we expect to have the edge, $w_1 \Rightarrow w_2$. Namely, in this case, $w_1 \Rightarrow w_2$ means that the vertices associated to w_1 and w_2 belong to the same connected component of the polytope when blow-ups are removed. In particular this implies that the number of connected components, say N_c , in the negative polytope Γ_- is bounded below by the number of connected component, say N_g , of the graph \mathcal{G} ; i.e. we expect $N_g \leq N_c$. For type A_l we have directly verified the equality $N_c = N_g$ for l = 1, 2, 3, 4 ($N_g = N_c$ in A_3 can be obtained from Figures 4 and 5), we expect the equality to be true for all l, and in the negative polytope Γ_- . However, for the case of B_3 , we have $N_c = 18$ and $N_g = 17$. Finding the precise numbers of N_c and N_g is a very interesting problem. We can classify the connected components in the negative polytope by dividing them into families according to the signs of a_i $i = 1, \ldots, l$ (see Figures 2 and 3). If we consider only negative components, that is, components where $a_i < 0$ for all i, then computations suggest that there are exactly 2^g negative components with $g := \operatorname{rank}(\check{K})$. This is the sum of all the Betti numbers of \check{K} . This formula works also in B_3 and "explains" the discrepancy between N_c and N_g in this case.

Summarizing: in many cases the graph \mathcal{G}_{ϵ} accomplishes the job of joining together in its connected components exactly those vertices w of the polytope Γ_{ϵ} belonging to the same connected components. This will be the case in the example considered below.

Example 3.5. In the case of A_2 , we have $s_1(--) = (-+)$, $s_2(-+) = (-+)$ which implies $(--) \rightarrow (-+) \stackrel{s_2}{\Longrightarrow} (-+)$ and $\eta(s_1) = 1$, $\eta(s_1s_2) = 1$. Therefore the graph \mathcal{G} which encodes blow-up information in Γ_{--} of Figure 2 is $(s_i \text{ is replaced with } i)$:

where the elements of the Weyl group are denoted by $s_i \cdots s_j = [i \cdots j]$. Here we have also listed the monomials $q^{\eta(w)}$ (in the variable q) associated to representatives of the integral cohomology $(w \to \eta(w) \to q^{\eta(w)})$. As already noted, the vertices of the hexagon Γ_{--} belonging to a connected component in Figure 2 form a connected component of this graph (see also Figure 1). This graph classifying connected components in the hexagon minus the blow-ups agrees with the graph in p.465 of [7] which is defined very differently in terms of incidence numbers. The graph of incidence numbers gives rise to a chain complex by replacing the edges \Rightarrow with multiplication by ± 2 ,

$$\mathbb{Z}\langle e\rangle \xrightarrow{\delta_0} \mathbb{Z}\langle s_1 \rangle \oplus \mathbb{Z}\langle s_2 \rangle \xrightarrow{\delta_1} \mathbb{Z}\langle s_1 s_2 \rangle \oplus \mathbb{Z}\langle s_2 s_1 \rangle \xrightarrow{\delta_2} \mathbb{Z}\langle s_1 s_2 s_1 \rangle \,.$$

Here $\langle w \rangle$ is the Bruhat cell associated to the element $w \in W$. The only non-zero map is δ_1 given by a diagonal matrix with 2's in the diagonal corresponding to the \Rightarrow . The integral cohomology that results is

$$\begin{cases} H^0(G/B;\mathbb{Z}) &= \mathbb{Z} &: q^0 \\ H^1(G/B;\mathbb{Z}) &= 0 &: q^1 \\ H^2(G/B;\mathbb{Z}) &= \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z} &: q^1 \\ H^3(G/B;\mathbb{Z}) &= \mathbb{Z} &: q^2 \end{cases}$$

Over the rationals this just gives the cohomology of K = SO(3) which can be written as the exterior ring with one generator x_1 of degree 2, i.e. $H^*(SO(3); \mathbb{Q}) = \Lambda(x_1q^2)$. The alternating sum of the $q^{\eta(w)}$ produces the polynomial $p(q) = q^2 - 1$. Now p(q) multiplied by q^r with $r := \dim(K) - \deg(p(q)) = 1$ gives the number of points of SO(3) over a field with q elements, i.e. $q^r p(q) = |SO(3; \mathbb{F}_q)|$ (q is a power of an odd prime p, and r is the number of positive roots associated with the group K, [5]). The explanation for this is that the $q^{\eta(w)}$ listed are Frobenius eigenvalues in etale cohomology of the appropriate varieties reduced to a field of positive characteristic (see p.465 of [7]). When this is taken into account we see that, in fact, more than the cohomology of K/T or K, we are obtaining etale \mathbb{Q}_m cohomology over a field of positive characteristic, including Frobenius eigenvalues. All are derived from the structure of the Toda lattice and its blow-up points. This is analogous to the situation described in Section 6.2 for the case of A_3 .

If we start with $\epsilon = (-+)$ then we obtain the edges $e \Rightarrow s_2$, $s_1 \Rightarrow s_2s_1$, $s_1s_2 \Rightarrow s_1s_2s_1$. This time the vertices of the hexagon Γ_{-+} belonging to a connected component in Figure 2 form a connected commponent of this graph. This graph now corresponds to the graph of incidence numbers computing cohomology with local coefficients. The local system can be described by the signs (-+). The – sign indicates that along a circle in G/B that corresponds to s_1 , the local system is constant, and the second sign + indicates that along a circle corresponding to s_2 , it is non-trivial. This can be made precise below and is an important step towards the dictionary. The cohomology one obtains from this graph associated to Γ_{-+} is the following:

$$\begin{cases} H^0(G/B;\mathcal{L}) &= 0\\ H^1(G/B;\mathcal{L}) &= \mathbb{Z}/2\mathbb{Z}\\ H^2(G/B;\mathcal{L}) &= \mathbb{Z}/2\mathbb{Z}\\ H^3(G/B;\mathcal{L}) &= \mathbb{Z}/2\mathbb{Z} \end{cases}$$

Here we did not list the powers $q^{\eta(w,-+)}$ but clearly $p_{-+}(q) = 0$ (Proposition 3.1), which implies that the rational cohomology with twisted coefficients \mathcal{L} is zero. Similarly we have the same results for Γ_{+-} and Γ_{++} .

In the case of a Lie algebra of type A_3 we obtain the graph \mathcal{G} in Figure 4. This graph corresponds to the polytope in Figure 5 as separated into connected components by the divisors shown. To determine the number $\eta(w)$ for any given w it is enough to go from e to w along any path along

FIGURE 4. The graph \mathcal{G} of the real flag manifold for type A_3 . The Bruhat cells NwB/B are denoted by $[ij \dots k]$ for $w = s_i s_j \dots s_k$. The incidence numbers associated with the edges \Rightarrow are ± 2 (see also Example (8.1) in [7]). There are 10 connected components in this graph corresponding to the 10 connected components in Γ_{-} after blow-up points are removed.

FIGURE 5. The Γ_{-} -polytope for type A_3 and the Painlevé divisors (the right figure is the back view of the left one). The Painlevé divisors are shown by the dotted curve for \mathcal{D}_1 , by the light color one for \mathcal{D}_2 , and by the dark one for \mathcal{D}_3 . The double circles indicate the divisor $\mathcal{D}_{ij} = \mathcal{D}_i \cap \mathcal{D}_j$, which are all connected at the center of the polytope p_o . The numbers $\eta(w)$ are obtained by using any path from e to w along edges of the polytope, following the direction of the Toda flow, i.e. the path $w \to ws_i$ with $l(ws_i) = l(w) + 1$, and counting intersections with the Painlevé divisors. The incidence graph in Figure 4 can then be obtained from this Figure.

the boundary corresponding to a reduced expression $w = s_{n_1} \cdots s_{n_r}$ and count the number of intersections with the divisors. In Figure 5, we show the path following the expression $w_* = [123121]$, i.e. $e \to s_1 \to s_1 s_2 \to s_1 s_2 s_3 \to \cdots \to w_*$, with the arrows on the edges of the polytope.

We then state the following theorem showing the equivalence between the connected components in the polytopes Γ_{ϵ} and the graphs \mathcal{G}_{ϵ} of the incidence numbers defined in [7]. A proof of the theorem will be given in Section 5.

Theorem 3.6. The graph \mathcal{G} is the graph of incidence numbers for the integral cohomology of the real flag manifold $\check{\mathcal{B}}$ in terms of the Bruhat cells. In general, each \check{K} -equivariant local system \mathcal{L} on $\check{\mathcal{B}}$ corresponds to an ϵ and \mathcal{G}_{ϵ} is the graph of incidence numbers for cohomology of $\check{\mathcal{B}}$ with twisted coefficients in \mathcal{L} .

Remark 3.7. In general there may be some signs ϵ such that no \tilde{K} -equivariant local system \mathcal{L} corresponds to it. For instance if $G = SL(4; \mathbb{R})$ this is the case. By considering the (possibly disconnected) group $\tilde{G} = \mathrm{Ad}(SL(4; \mathbb{R})^{\pm})$ (see Remark 2.1) this difficulty disappears; this is mostly

due to the fact that $H_{\mathbb{R}}$, the Cartan subgroup of \tilde{G} , has 2^l connected components which are not related by central elements.

4. Real flag manifold K/T and topology of K

For each real split simple Lie algebra \mathfrak{g} we have defined a connected Lie group G and a maximal compact Lie subgroup K (fixed point sets of a Cartan involution θ). Moreover in the appropriate context of algebraic groups, all these objects can also be considered over a field k, an algebraic closure of a finite field \mathbb{F}_q with q elements. We also recall that the real flag manifold is first replaced with a complex manifold \mathcal{O}_o , a $K(\mathbb{C})$ -orbit in the complex flag manifold $\mathcal{B}_{\mathbb{C}}$.

We now consider the K-equivariant local systems on G/B and \mathcal{O}_o which arise from the volume forms on the Bruhat cells. These determine the incidence numbers in a chain complex that computes integral cohomology of G/B in [7]. The tangent space of the Bruhat cell associated to an element $w \in W$ is given by $w\mathfrak{n}^* \cap \mathfrak{n}$. The cotangent space then corresponds to $w\mathfrak{n} \cap \mathfrak{n}^*$. Now $\Lambda^{l(w)}w\mathfrak{n} \cap \mathfrak{n}^*$ represents a volume form on the Bruhat cell. From here we can also obtain l(w)-forms on G/Bwhich are part of a de Rham chain complex. The action of T on each $\Lambda^{l(w)}w\mathfrak{n} \cap \mathfrak{n}^*$ determines a K-equivariant local system. These local systems arising from those forms associated to Bruhat cells determine the incidence numbers with respect to (dual) of Bruhat cells. Moreover the local systems determined by the $\Lambda^{l(w)}w\mathfrak{n} \cap \mathfrak{n}^*$ correspond to the signs $\epsilon_i = \operatorname{sgn}(a_i)$ on the connected components of the Γ_- -polytope.

Example 4.1. Case of SL(2;k). There are two K(k)-equivariant local systems on k^* corresponding to the characters of a two element group $T = \left\{ \begin{pmatrix} \epsilon_1 & 0 \\ 0 & \epsilon_1 \end{pmatrix} \middle| \epsilon_1 = \pm 1 \right\}$. The trivial character gives a constant sheaf \mathcal{C} and the non-trivial character gives a non-trivial local system \mathcal{L} . Note that in this case T acts trivially on $\Lambda^{l(w)}w\mathfrak{n} \cap \mathfrak{n}^*$. For example if $w = s_1, \Lambda^1 s_1\mathfrak{n} \cap \mathfrak{n}^* = \mathbb{R}X_{e_1-e_2}, (\alpha_1 = e_1 - e_2)$ and T acts trivially on $X_{e_1-e_2} = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$.

The two local systems described correspond to the connected components in Γ_- for the $\mathfrak{sl}(2;\mathbb{R})$ case of the example in Introduction. The non-trivial local system corresponds to the single component Γ_+ . Tensoring with $\Lambda^{l(w)}w\mathfrak{n}\cap\mathfrak{n}^*$ produces the signs in Γ_+ , we obtain for $w = s_1$, $\epsilon_1 =$ $\operatorname{sgn}(a_1) = +$ corresponding to no blow-ups and to a non-trivial local systems in G/B.

We now make precise the correspondence between the various polytopes Γ_{ϵ} and the computation of cohomology with local coefficients of G/B.

4.1. Volume forms on the Bruhat cells and local systems. In [7] a chain complex of differential forms analogous to the de Rham chain complex is used. The differential forms are sections of the line bundle on the flag manifold K/T induced by the action of T on $\Lambda^{l(w)}w\mathfrak{n} \cap \mathfrak{n}^*$. The approach in [7] is to relate the boundaries in the chain complex to the representation theory of the non-compact Lie group G acting on these sections. Recall that a $K(\mathbb{C})$ -equivariant local system on \mathcal{O}_o is given by a character of T. If H_+ is a split Cartan subgroup in G with connected component of the identity, then H/H_+ is isomorphic to T. Therefore, since the Weyl group W acts on both H and H_+ , it also acts on T. From here it follows that W acts on the characters of T. Given $\chi : T \to \{\pm 1\}$ character of T, we denote $w(\chi)$ the character obtained by applying w to χ . We will define a function ϵ associating to each K-equivariant local system \mathcal{L} on $\check{\mathcal{B}}$ a list of l signs ϵ . The action of W on the characters of T is just the action of W on signs which was introduced earlier (Definition 2.10).

Definition 4.2. Given the $K(\mathbb{C})$ -equivariant local system \mathcal{L} corresponding to a character of T given by $\chi(\mathcal{L})$ we define \mathcal{L}_w to be the $K(\mathbb{C})$ -equivariant local system on \mathcal{O}_o determined by the action of T on $\chi(\mathcal{L}) \otimes \Lambda^{l(w)} \mathfrak{wn} \cap \mathfrak{n}^*$.

We now consider a parabolic subgroup P_i with complexification $P_i(\mathbb{C})$ associated to a simple root α_i containing the Borel subgroup B of G. There are projections: $\pi_i : G(\mathbb{C})/B(\mathbb{C}) \to G(\mathbb{C})/P_i(\mathbb{C})$ and $\pi_i : G/B \to G/P_i$. Then restricting the local system \mathcal{L} to the fibers of π_i can be described as follows: Recall that the fibers of π_i are \mathbb{P}^1 , that is, the flag manifold obtained from $SL(2;\mathbb{C})$. Each

simple root α_i gives rise to a Lie group map, $\Phi_{\alpha_i} : SL(2; \mathbb{R}) \to G$. We consider $\Phi_{\alpha_i}\begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix} \in T$. Similarly we have maps $\Phi_{w\alpha_i}$ for $w \in W$.

Proposition 4.1. The local system \mathcal{L}_w is trivial along the fiber of π_i containing x_w if and only if the character $\chi_w(\mathcal{L})$ of T on $w^{-1}\chi(\mathcal{L}) \otimes \Lambda^{l(w)} \mathfrak{n} \cap w^{-1}\mathfrak{n}^*$ is trivial on $z_i = \Phi_{\alpha_i}(\begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}).$

Proof. The local system \mathcal{L}_w is trivial along the fiber of π_i containing x_w if and only if the character of T on $\chi(\mathcal{L}) \otimes \Lambda^{l(w)} w \mathfrak{n} \cap \mathfrak{n}^*$ is trivial on $\Phi_{w\alpha_i}\begin{pmatrix} -1 & 0\\ 0 & -1 \end{pmatrix}$). Translating by w^{-1} everything we obtain our statement.

We now recall that $T = K \cap B = K(\mathbb{C}) \cap B(\mathbb{C})$ is a finite group, and the characters $\chi: T \to \{\pm\}$ parametrize $K(\mathbb{C})$ -equivariant local systems. We will now find a more convenient of expressing these local systems in terms of l signs which keep track of their structure along certain directions given by the simple roots.

Definition 4.3. We let $\epsilon(w, \mathcal{L}) = (-\chi_w(\mathcal{L})(z_1), \dots, -\chi_w(\mathcal{L})(z_l))$. If \mathcal{L} is trivial we just write $\epsilon(w, \mathcal{L}) = \epsilon(w).$

Note here that a constant sheaf \mathcal{L} corresponds to a sign $\epsilon(w, \mathcal{L}) = (- \dots -)$. With this parametrization we will have a correspondence in which a polytope Γ_{ϵ} corresponds to the choice of a local system \mathcal{L} whose sign $\epsilon(e, \mathcal{L}) = \epsilon$. The signs of the a_i appearing inside the polytope will agree with the various $\epsilon(w, \mathcal{L})$ derived from the volume forms on the Bruhat cells for a fixed \mathcal{L} (e.g. the trivial sheaf \mathcal{L}) in the dual flag manifold \mathcal{B} . This is shown in Proposition 5.1. There we show that for fixed \mathcal{L} the set of signs $\{\epsilon(w, \mathcal{L}) \mid w \in W\}$ is a W-orbit. Since the signs $\{(\operatorname{sgn}(a_1) \dots \operatorname{sgn}(a_l))\}$ corresponding to the polytope $\Gamma_{\epsilon(w,\mathcal{L})}$ are also given by the same W-orbit, a correspondence is established between local systems associated to a fixed set of local coefficients \mathcal{L} , and the signs appearing from the Toda lattice associated to a fixed polytope $\Gamma_{\epsilon(w,\mathcal{L})}$. This is part of the "partial dictionary".

4.2. The graphs of incidence numbers of the real flag manifold. We first review the computation of integral cohomology of G/B with certain K-equivariant local coefficients:

Recall that there is filtration by Bruhat cells with $\mathcal{B}_i := \bigcup_{l(w) \leq i} NwB/B$,

$$\emptyset \subset \mathcal{B}_0 \subset \mathcal{B}_1 \subset \cdots \subset \mathcal{B}_{l(w_*)} = G/B$$

Then there are coboundary maps $\delta: H^s(\mathcal{B}_s, \mathcal{B}_{s-1}; \mathbb{Z}) \to H^{s+1}(\mathcal{B}_{s+1}, \mathcal{B}_s; \mathbb{Z})$ which give rise to a chain complex computing the cohomology of G/B (as in [18] Theorem 39.4). We have $H^s(\mathcal{B}_s, \mathcal{B}_{s-1}; \mathbb{Z}) =$ $\operatorname{Hom}_{\mathbb{Z}}(H_s(\mathcal{B}_s, \mathcal{B}_{s-1}; \mathbb{Z}), \mathbb{Z}).$ Also $H_s(\mathcal{B}_s, \mathcal{B}_{s-1}; \mathbb{Z}) = \bigoplus_{l(w)=s} H_s(\overline{\mathcal{B}}_w, \overline{\mathcal{B}}_w \setminus \mathcal{B}_w).$ Denote [w] the homology class that corresponds to \mathcal{B}_w . Generators of $H^{s+1}(\mathcal{B}_{s+1}, \mathcal{B}_s; \mathbb{Z})$ can then be given by the Z-module maps f_w with $w \in W$ such that l(w) = s determined by $f_w([w']) = 0$ if $w \neq w'$ and $f_w([w]) = 1$. The coboundary can be written in the form, $\delta(f_w) = \sum_{l(w')=s+1} [w;w'] w'$. The incidence numbers are known to be 0 or ± 2 (see [7]).

Definition 4.4. We define a graph $\mathcal{G}_{\mathcal{B}}$ whose vertices consists of the elements in W and oriented edges $w \Rightarrow w'$ if and only if $[w; w'] \neq 0$, i.e. $\mathcal{G}_{\mathcal{B}}$ is the graph of incidence numbers associated with $H^*(\mathcal{B};\mathbb{Z})$. If local coefficients given by a locally constant sheaf \mathcal{L} are used, then we denote the graph of incidence numbers leading to $H^*(\mathcal{B};\mathcal{L})$ by $\mathcal{G}_{\mathcal{L},B}$.

We now can rewrite Definition 7.4 b) of [7] for the real split cases in terms of these signs. This will lead to the definition of an oriented graph whose vertices are the elements of W.

Definition 4.5. We fix \mathcal{L} and recall that the sign associated to \mathcal{L}_w is $\epsilon(w, \mathcal{L}) = (\epsilon_1 \dots \epsilon_l)$. We then define $w \stackrel{\mathcal{L}}{\Longrightarrow} ws_i$ if and only if $\epsilon_i = +$, that is, the local system \mathcal{L}_w is nontrivial along the fiber of π containing x_w . In addition, if x increases the length of both w and ws_i and $w \stackrel{\mathcal{L}}{\Longrightarrow} ws_i$, then we also have an edge $wx \stackrel{\mathcal{L}}{\Longrightarrow} ws_i x$.

We now define the number $z(w, \mathcal{L})$, which is given in a way that is parallel to Definition 2.10 for the $\eta(w, \epsilon)$ computing the number of blow-ups along the Toda flow. However the ϵ keeping track of a polytope Γ_{ϵ} is replaced with $\epsilon(e, \mathcal{L})$ keeping track of a local system, and each \Rightarrow is replaced with $\stackrel{\mathcal{L}}{\Longrightarrow}$ i.e. a non-zero incidence number. Hence in $z(w, \mathcal{L})$, we take into account not simple reflections that represent the crossing of a blow-up, but rather simple reflections that give a non-trivial coboundary.

Definition 4.6. For any reduced expression $w = s_{j_1} \cdots s_{j_{l(w)}}$, we have $s_{j_1} \cdots s_{j_r} \to s_{j_1} \cdots s_{j_r} s_{j_{r+1}}$ for $r = 1, \dots, l(w) - 1$. We let $z(w, \mathcal{L})$ denote the number of all \to obtained as r varies over $r = 1, \dots, l(w) - 1$ which are *not* of the form $\stackrel{\mathcal{L}}{\Longrightarrow}$.

Remark 4.7. The numbers $z(w, \mathcal{L})$ have the following algebraic description ([6, 7]). Consider the set \mathcal{D} of all $K(\mathbb{C})$ -equivariant local systems on all the $K(\mathbb{C})$ -orbits in $G(\mathbb{C})/B(\mathbb{C})$. Then as in [16], the set \mathcal{M} of formal linear combinations of elements in \mathcal{D} with coefficients in $\mathbb{Z}[q, q^{-1}]$, $\mathcal{M} = \mathbb{Z}[q, q^{-1}] \otimes_{\mathbb{Z}} \mathbb{Z}[\mathcal{D}]$, becomes a module over the Hecke algebra $\mathcal{H} = \mathbb{Z}[q, q^{-1}] \otimes_{\mathbb{Z}} \mathbb{Z}[W]$, that is, the set \mathcal{H} of formal linear combinations of elements in W with coefficients in $\mathbb{Z}[q, q^{-1}]$. If we denote by T_w an element w viewed inside \mathcal{H} , then the action of T_w on any local system is determined by formulas describing the action of the $T_{s_i}\mathcal{L}$ for the simple roots s_i . These formulas are given in p.371 of [16] and if $w = s_{j_1} \cdots s_{j_k}$ is a reduced expression and $m \in \mathcal{M}$, then $T_w m = T_{s_{j_1}} \cdots T_{s_{j_k}} m$ is independent of the reduced expression.

We now express $z(w, \mathcal{L})$ in terms of the action of the Hecke algebra operators T_w . If $\mathcal{L} \in \mathcal{D}$ is a local system on \mathcal{O}_o , we have that $T_{w^{-1}}^{-1}\mathcal{L}$ is a linear combination of elements in the set of \mathcal{D} . Under our assumptions (i.e. real split Lie algebras and groups) $T_{w^{-1}}^{-1}\mathcal{L}$, which gives the graded character of a principal series module relative to its weight filtration, contains exactly one $K(\mathbb{C})$ -equivariant local systems on the open orbit \mathcal{O}_o with non-zero coefficient (see [6, 7]). This coefficient is $\pm q^{-z(w,\mathcal{L})}$. This implies that $z(w, \mathcal{L})$ is independent of the choice of a reduced expression (because T_w is independent of a reduced expression).

Example 4.8. In the case of $SL(2; \mathbb{R})$ (see Example 4.1), $\mathcal{D} = \{\mathcal{C}, \mathcal{L}, \delta_+, \delta_-\}$ where \mathcal{C} denotes a trivial sheaf on $\mathcal{O}_o = \mathbb{C}^*$, δ_{\pm} are sheaves supported on the points 0, ∞ respectively, and \mathcal{L} is a non-trivial local system on \mathbb{C}^* . We have $T_{s_1}\mathcal{C} = (q-2)\mathcal{C} + (q-1)(\delta_- + \delta_+)$ and $T_{s_1}\mathcal{L} = -\mathcal{L}$. We now compute the numbers $z(s_1, \cdot)$ in terms of the Hecke algebra operators. In the Hecke algebra $T_{s_1}^{-1} = q^{-1}(T_{s_1} + (1-q))$. Hence by applying $T_{s_1}^{-1}$ to \mathcal{C} we obtain $-q^{-1}\mathcal{C} + q^{-1}(q-1)(\delta_+ + \delta_-)$. Thus the coefficient of \mathcal{C} is $-q^{-z(s_1,\mathcal{C})}$ with $z(s_1,\mathcal{C}) = 1$. We also have $q^{-1}(T_{s_1}\mathcal{L} + (1-q)\mathcal{L}) = q^{-1}(-\mathcal{L} + (1-q)\mathcal{L}) = -\mathcal{L}$. Hence $z(s_1,\mathcal{L}) = 0$. Note that these numbers extracted from the Hecke algebra operators defined in [16] correspond to the number of blow-ups in the Toda lattice in the A_1 case as represented in Figure 1 (in Γ_- , Γ_+ respectively). See Corollary 5.1 below for a general statement.

Finally, we note the connection with the $\mathfrak{sl}(2,\mathbb{R})$ example in Introduction. By rewriting $T_{s_1}^{-1}q^1\mathcal{C}$ as $-q^{-1/2}\hat{C}_{\mathcal{C}}+\hat{C}_{\delta_+}+\hat{C}_{\delta_-}$ with $\hat{C}_{\mathcal{C}}=q^{-1/2}(\mathcal{C}+\delta_++\delta_-)$, $\hat{C}_{\delta_{\pm}}=\delta_{\pm}$, we recover the weight filtration of the module denoted $F^{even}(S^1)$ (replace $\hat{C}_{\mathcal{C}}$ with C and $\hat{C}_{\delta_{\pm}}$ with D_{\pm} and shift the weights there by $q^{-1/2}$). The structure of the module Ω^{even} arises from \mathcal{C} , and the (irreducible) $F^{odd}(S^1)$ corresponds to \mathcal{L} .

Proposition 4.2. The numbers $z(w, \mathcal{L})$ are independent of the reduced expression used in Definition 4.6.

Proof. The argument follows from the formula in Remark 4.7 above expressing $z(w, \mathcal{L})$ in terms of the action of a Hecke algebra operator T_w , action which is independent of a reduced expression. The number $q^{z(w,\mathcal{L})}$ with q a power of a prime is also interpreted below (and in [7]) as a Frobenius eigenvalue attached to a Bruhat cell, that is, attached to a Weyl group element w. Again from this second interpretation, it follows that the number $z(w,\mathcal{L})$ is independent of a reduced expression. These two arguments are related because the formulas in p.371 of [16] ultimately arise from calculations that involve Frobenius eigenvalues. \Box

We can now rewrite the description of the graph of incidence numbers in [7] as follows:

Theorem 4.9. The graph of incidence numbers $\mathcal{G}_{\mathcal{L},B}$ coincides with the graph obtained from Definition 4.5.

Proof. This theorem is proved in [7] in representation theoretic terms and corresponds to a similar result in [13] written in terms of different parameters. We give a geometric argument only in the case $w \Rightarrow ws_i$. Consider $\mathcal{B}_w \cup \mathcal{B}_{ws_i}$ a union of two N-orbits which can be seen as a circle bundle over \mathcal{B}_w . We fix a circle, a fiber of π_i containing x_w , and regard this set $\mathcal{B}_w \cup \mathcal{B}_{ws_i}$, this time as a bundle over this circle. The fibers correspond to copies of \mathcal{B}_w . By considering the volume forms $\Lambda^{l(w)}w\mathfrak{n} \cap \mathfrak{n}^*$ the bundle becomes a line bundle over a circle, that is, either a cylinder or a Möbius band. Determining the coefficient of the boundary of \mathcal{B}_{ws_i} along \mathcal{B}_w then becomes a question about the triviality or non-triviality of this bundle. If the bundle is non-trivial then there is a change in the orientation of the volume form around the circle and this gives rise to a ± 2 . \square

Example 4.10. Consider $G = SL(3; \mathbb{R})$, K = SO(3) and \mathcal{L} as determined by the character defined by the action of T acting by $e_1e_2^{-1}$ (action on root vector for $e_1 - e_2$). Since we are applying the character to $e_i = \pm 1$, we can just write this character as $\chi(\mathcal{L}) = e_1e_2$. We then have $s_1(e_1e_2) = e_1e_2$, $s_2(e_1e_2) = e_1e_3$, $s_2s_1(e_1e_2) = e_1e_3$, $s_1s_2(e_1e_2) = e_2e_3$ and $s_1s_2s_1(e_1e_2) = e_2e_3$. We write the characters of $\Lambda^{l(w)} \mathfrak{n} \cap w^{-1} \mathfrak{n}^*$, and obtain, for $w = e, \mathfrak{n} \cap \mathfrak{n}^* = 0$ with $\chi_{e} = 1$; for $w = s_1$, $\mathfrak{n} \cap s_1\mathfrak{n}^* = \mathbb{R}X_{e_1-e_2}$ with $\chi_{s_1} = e_1e_2$; for $w = s_2$, $\mathfrak{n} \cap s_2\mathfrak{n}^* = \mathbb{R}X_{e_2-e_3}$ with $\chi_{s_2} = e_2e_3$; for $w = s_1s_2$, $\mathfrak{n} \cap s_2\mathfrak{n}\mathfrak{n}^* = \mathbb{R}X_{e_1-e_2} \oplus \mathbb{R}X_{e_1-e_3}$ with $\chi_{s_1s_2} = e_1e_2$; for $w = s_2s_1, \mathfrak{n} \cap s_1s_2\mathfrak{n}^* = \mathbb{R}X_{e_1-e_2} \oplus \mathbb{R}X_{e_1-e_3}$ with $\chi_{s_2s_1} = e_2e_3$; and for $w = s_1s_2s_1, \mathfrak{n} \cap s_1s_2s_1\mathfrak{n}^* = \mathbb{R}X_{e_1-e_2} \oplus \mathbb{R}X_{e_1-e_3}$ with $\chi_{s_1s_2} = e_1e_2$; for $w = s_2s_1, \mathfrak{n} \cap s_1s_2\mathfrak{n}^* = \mathbb{R}X_{e_1-e_2} \oplus \mathbb{R}X_{e_1-e_3}$ with $\chi_{s_1s_2s_1} = e_2e_3$; and for $w = s_1s_2s_1, \mathfrak{n} \cap s_1s_2s_1\mathfrak{n}^* = \mathbb{R}X_{e_1-e_3} \oplus \mathbb{R}X_{e_1-e_3} \oplus \mathbb{R}X_{e_1-e_3}$ with $\chi_{s_1s_2s_1} = 1$. Evaluating $\Phi_{\alpha_1}(\begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix})$ in these characters then means substituting $e_1 = -1, e_2 = -1, e_3 = 1$ and evaluating $\Phi_{\alpha_2}(\begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix})$ corresponds to substituting $e_1 = 1, e_2 = -1, e_3 = -1$. For example $\epsilon(s_1s_2)$ is the pair $(-e_1e_2, -e_1e_2)$ in which we replace $e_1 = -1, e_2 = -1$ in the first coordinate and $e_1 = 1, e_2 = -1$ in the second thus obtaining (-+). Therefore we obtain: $\epsilon(e) = (--), \epsilon(s_1) = (-+), \epsilon(s_2) = (+-), \epsilon(s_1s_2) = (-+), \epsilon(s_2s_1) = (+-), \epsilon(s_1s_2s_1) = (--)$. From here it follows that the graph $\mathcal{G}_{\mathcal{B}}$ contains the following edges, $s_1 \Rightarrow s_1 s_2$ and $s_2 \Rightarrow s_2 s_1$. Therefore the graph $\mathcal{G}_{\mathcal{B}}$ which is the one derived earlier from the blow-ups of the Toda lattice in Example 3.5, i.e.

We now tensor with $w^{-1}\chi(\mathcal{L})$ and obtain the list of $\chi_w(\mathcal{L}) = w^{-1}\chi(\mathcal{L}) \otimes \chi_w$: $\chi_e(\mathcal{L}) = e_1e_2$, $\chi_{s_1}(\mathcal{L}) = e_1e_2 \otimes e_1e_2 = 1$, $\chi_{s_2}(\mathcal{L}) = e_2e_3 \otimes e_1e_3 = e_1e_2$, $\chi_{s_1s_2}(\mathcal{L}) = e_1e_2 \otimes e_1e_3 = e_1e_2 = e_2e_3$, $\chi_{s_2s_1}(\mathcal{L}) = e_2e_3 \otimes e_2e_3 = 1$. $\chi_{s_1s_2s_1}(\mathcal{L}) = 1 \otimes e_2e_3 = e_2e_3$. Therefore we obtain: $\epsilon(e, \mathcal{L}) = (-+)$, $\epsilon(s_1, \mathcal{L}) = (--)$, $\epsilon(s_2, \mathcal{L}) = (-+)$, $\epsilon(s_1s_2, \mathcal{L}) = (+-)$, $\epsilon(s_2s_1, \mathcal{L}) = (--)$, $\epsilon(s_1s_2s_1, \mathcal{L}) = (+-)$.

Now the graph $\mathcal{G}_{\mathcal{L},B}$ has the following edge: $e \stackrel{\mathcal{L}}{\Longrightarrow} s_2$. Since s_1 increases the length of both vertices we also must have $s_1 \stackrel{\mathcal{L}}{\Longrightarrow} s_2 s_1$ and using that s_2 increases the length of both vertices $s_1 s_2 \stackrel{\mathcal{L}}{\Longrightarrow} s_2 s_1 s_2$. We obtain the second graph $\mathcal{G}_{(-+)}$ discussed in Example 3.5.

5. Proof of Theorem 3.6

Now we give a proof of Theorem 3.6 which provides the connection between the Toda lattice and the cohomology of real flag manifold by showing that the graphs \mathcal{G}_{ϵ} are the graphs of the incidence numbers for cohomology of the flag manifold $\check{\mathcal{B}}$. Let us begin with the following Proposition:

Proposition 5.1. For $\epsilon(w, \mathcal{L}) = (\epsilon_1 \dots \epsilon_l)$, we have $\epsilon(ws_i, \mathcal{L}) = (\epsilon'_1 \dots \epsilon'_l)$ where $\epsilon'_j = \epsilon_j \epsilon_i^{C_{i,j}}$.

Proof. We have $\mathbf{n} \cap s_i w^{-1} \mathbf{n}^* = \mathbf{n} \cap w^{-1} \mathbf{n}^* \oplus \mathbb{R} X_{\alpha_i}$, where X_{α_i} is a root vector. Therefore $\Lambda^{l(w)+1} \mathbf{n} \cap s_i w^{-1} \mathbf{n}^* = \Lambda^{l(w)} \mathbf{n} \cap w^{-1} \mathbf{n}^* \wedge \mathbb{R} X_{\alpha_i}$. Hence the character of T given by $\Lambda^{l(w)} \mathbf{n} \cap w^{-1} \mathbf{n}^*$ changes exactly by the character χ_{α_i} corresponding to the action of T on the root vector X_{α_i} . The evaluation of χ_{α_i} on $\Phi_{\alpha_j}\begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}$ is given by $e^{<\alpha_i;\sqrt{-1}\pi h_{\alpha_j}>}$ that is as $e^{\sqrt{-1}\pi C_{i,j}}$. Hence we obtain $\epsilon_j \to \epsilon_j \epsilon_i^{C_{i,j}}$. \Box

Note that the action of s_i on the signs in Proposition 5.1 is different from the action of s_i on signs of the Toda lattice in Definition 2.9. The difference is that in the case of the Toda lattice with

 $C_{j,i}$, the transpose of $C_{i,j}$ is involved; because of this, the Lie algebra $\check{\mathfrak{g}}$ is involved. Thus the set of signs $\{\epsilon(w,\mathcal{L}) \mid w \in W\}$ is the *W*-orbit of the signs $\epsilon(e,\mathcal{L})$ with the *W*-action defined with respect to the Lie algebra $\check{\mathfrak{g}}$ (Definition 2.9). This is also the set of signs $(\operatorname{sgn}(a_1) \dots \operatorname{sgn}(a_l))$ that occur in the polytope $\Gamma_{\epsilon(e,\mathcal{L})}$ with respect to the Lie algebra $\check{\mathfrak{g}}$. For example, in the case in which \mathfrak{g} is a Lie algebra of type *B*, the signs in a polytope in the isospectral manifold of the Toda lattice correspond to a Lie algebra of type *C*.

The following proposition will then relate the Frobenius eigenvalues $q^{z(w,\mathcal{L})}$ appearing in the cohomology of $\mathcal{B}(k_q)$ with the numbers $\check{\eta}(w, \epsilon(\mathcal{L}, w))$ for the Toda lattice associated to the Lie algebra $\check{\mathfrak{g}}$.

Proposition 5.2. Assume that g is a semisimple real split Lie algebra then $z(w, \mathcal{L}) = \check{\eta}(w, \epsilon(w, \mathcal{L}))$.

Proof. By Proposition 5.1 the set of signs $\{\epsilon(w, \mathcal{L}) \mid w \in W\}$ keeping track of triviality or nontriviality of the local systems \mathcal{L}_w along certain fibers of π_i is just the W-orbit of the sign $\epsilon(e, \mathcal{L})$. This is just the set of signs $(\operatorname{sgn}(a_1) \dots \operatorname{sgn}(a_l))$ in the polytope $\Gamma_{\epsilon(e,\mathcal{L})}$ for the Lie algebra $\check{\mathfrak{g}}$ as noted above. We then note that the condition for $w \Rightarrow ws_i$ in Definition 2.10 that $\epsilon_i = +$ corresponds to the non-triviality of the sheaf \mathcal{L}_w along the fiber of π_i containing x_w . From here it follows that $z(w,\mathcal{L}) = \check{\eta}(w,\epsilon(w,\mathcal{L}))$. \Box

We obtain the following expression for the numbers $\check{\eta}(w,\epsilon)$ in terms of Hecke algebra operators:

Corollary 5.1. If $\epsilon = \epsilon(e, \mathcal{L})$, then $\pm q^{-\check{\eta}(w, \epsilon)}$ is the coefficient of \mathcal{L} in $T_{w^{-1}}^{-1}\mathcal{L}$ in the module over the Hecke algebra in [16] (Remark 4.7).

Proof. This follows from Remark 4.7 coupled with Proposition 5.2.

In particular we recover the number of blow-ups $\eta(s_1, -) = \eta(s_1) = 1$ and $\eta(s_1, +) = 0$ in the $\mathfrak{sl}(2; \mathbb{R})$ case from the action of the Hecke algebra operator T_{s_1} as in Example 4.8.

Corollary 5.2. The number $\eta(w, \epsilon)$ is independent of a reduced expression of w.

Proof. This follows from Corollary 5.1 or directly from Proposition 5.2 because the numbers $z(w, \mathcal{L})$ are independent of a reduced expression of w (Proposition 4.2). It is possible to choose the group G so that all possible ϵ are of the form $\epsilon(e, \mathcal{L})$ (\tilde{G} in Remark 2.1 or in [8]). \Box

The following Proposition completes the proof of Theorem 3.6 (see Definition 3.4 for \mathcal{G}_{ϵ}):

Proposition 5.3. We have $w_1 \stackrel{\mathcal{L}}{\Longrightarrow} w_2$ if and only if

- a) $w_1 \leq w_2$ in the Bruhat order,
- b) $l(w_2) = l(w_1) + 1$,
- c) $\check{\eta}(w_1, \epsilon(e, \mathcal{L})) = \check{\eta}(w_2, \epsilon(e, \mathcal{L})),$
- d) $\epsilon(w_1, \mathcal{L}) = \epsilon(w_2, \mathcal{L})$.

Proof. Note that $w_1 \leq w_2$ in the Bruhat order with $l(w_2) = l(w_1) + 1$ if and only if there are $a, x, s_i \in W$ such that $w_1 = ax, w_2 = as_i x$ and $l(axs_i) = l(a)+l(x)+1$. Hence, by definition, if a) and b) are satisfied $w_1 \stackrel{\mathcal{L}}{\Longrightarrow} w_2$ if and only if $a \stackrel{\mathcal{L}}{\Longrightarrow} as_i$. In turn this is true if and only if $z(a, \epsilon(a, \mathcal{L})) = z(as_i, \epsilon(a, \mathcal{L}))$. By Proposition 5.2, this is true if and only if $\check{\eta}(a, \epsilon(e, \mathcal{L})) = \check{\eta}(as_i, \epsilon(e, \mathcal{L}))$, and moreover, if and only if the signs $\epsilon(a, \mathcal{L})$ and $\epsilon(as_i, \mathcal{L})$ agree and the *i*th sign is + on both sides. Again by Proposition 5.2, since $\epsilon(ax, \mathcal{L})$ and $\epsilon(as_ix, \mathcal{L})$ are obtained by applying x^{-1} to $\epsilon(ax, \mathcal{L}) = \epsilon(as_ix, \mathcal{L})$, using the W-action we have $\check{\eta}(a, \epsilon(e, \mathcal{L})) = \check{\eta}(as_i, \epsilon(e, \mathcal{L}))$ if and only if $\check{\eta}(ax, \epsilon(e, \mathcal{L})) = \check{\eta}(as_ix, \epsilon(e, \mathcal{L}))$. Thus we conclude that whenever a) and b) are satisfied $w_1 \stackrel{\mathcal{L}}{\Longrightarrow} w_2$ if and only if $\check{\eta}(w_1, \epsilon(e, \mathcal{L})) = \check{\eta}(w_2, \epsilon(e, \mathcal{L}))$. \Box

Remark 5.1. Let $W^- = \{w \in W | w^{-1}(-\ldots -) = (-\ldots -)\}$. Note that under the correspondence between local K-equivariant local systems and signs $\mathcal{L} \to \epsilon(w, \mathcal{L})$, a trivial sheaf \mathcal{L} corresponds to an element in W^- . By Theorem 3.6 the vertices of the graph of incidence numbers belonging to W^- are the only ones that may contribute to rational cohomology.

LUIS CASIAN AND YUJI KODAMA*

6. RATIONAL COHOMOLOGY OF K AND p(q)

Here we first show that the number of blow-ups $\eta(w)$ for each $w \in W$ is given by the eigenvalues of the Frobenius map on the cohomology of flag manifold. We then show that the polynomial p(q)defined in Definition 3.1 is related to the order of Chevalley group $K(\mathbb{F}_q)$.

6.1. Frobenius eigenvalues and $\eta(w)$. Let us consider a filtration,

$$\emptyset \subset \mathcal{Y}_0 \subset \mathcal{Y}_1 \subset \cdots \subset \mathcal{Y}_{l(w_*)} = \mathcal{B}_{\mathbb{C}}$$

given by intersection of \mathcal{O}_o with the $N(\mathbb{C})$ cells inside $G(\mathbb{C})/B(\mathbb{C})$. We obtain coboundary maps, $H^j(\mathcal{Y}_j, \mathcal{Y}_{j-1}; \mathbb{C}) \to H^{j+1}(\mathcal{Y}_{j+1}, \mathcal{Y}_j; \mathbb{C})$ which give rise to a chain complex computing the cohomology of \mathcal{O}_o . For example in the case of SU(1, 1) above, $\mathcal{Y}_0 = \{\infty\}$ and $\mathcal{Y}_1 = \mathbb{C} \setminus \{0\}$. Each w corresponds to a dual of a Bruhat cell and contributes to the cohomology of $H^{l(w)}(\mathcal{Y}_{l(w)}, \mathcal{Y}_{l(w)-1}; \mathbb{C})$ giving rise to a cohomology class $[w]_{\mathbb{C}}$. This can be done with etale cohomology with coefficients in $\overline{\mathbb{Q}}_m$ and a field of positive characteristic. In this case a Frobenius action arises in cohomology.

We have the following proposition for the Frobenius eigenvalue of the cohomology class $[w]_{k_q}$ in etale cohomology over a field k_q algebraic closure of \mathbb{F}_q of characteristic p. This assumes $\overline{\mathbb{Q}}_m$ coefficients where m is relatively prime to p and $p \neq 2$ and $x^2 + 1$ factors over \mathbb{F}_q .

Proposition 6.1. The cohomology class $[w]_{k_q}$ in $H^{l(w)}(\mathcal{Y}_{l(w)}, \mathcal{Y}_{l(w)-1}; \overline{\mathbb{Q}}_m)$ corresponding to $w \in W$ has Frobenius eigenvalue given by $q^{\check{\eta}(w)}$.

Proof. This statement is obtained by expressing Proposition 9.5 in [7] in terms of new notation where local systems are expressed in terms of their signs $\epsilon(w, \mathcal{L})$. This corresponds to Corollary 5.1. The argument in Proposition 9.5 in [7] for the real split case reduces to the $\mathfrak{sl}(2;\mathbb{R})$ case and, strictly speaking, gives Frobenius eigenvalues up to a sign \pm . This choice of a sign corresponds to the two possibilities q-1 or q+1 for the number of points in $SO(2;\mathbb{F}_q)$. By assuming that \mathbb{F}_q contains $\sqrt{-1}$, the formula for the number of points is fixed as q-1, and thus the sign is fixed too as in Example 6.2 below, or the A_1 example given in Introduction .

The upshot of this is that the number of blow-ups $\eta(w)$ associated to a vertex w in the Toda lattice and the Frobenius eigenvalue of $[w]_{k_q}$ in $H^{l(w)}(\mathcal{Y}(k_q)_{l(w)}, \mathcal{Y}(k_q)_{l(w)-1}; \bar{\mathbb{Q}}_m)$ are given by the same formula in Definition 2.10. \square

Example 6.1. The case of SU(1,1): Recall in Example 2.6 that SU(1,1) corresponds to the real form of $SL(2;\mathbb{C})$. In this case the number of \mathbb{F}_q points in $\mathcal{O}_o(k)$ equals q-1. This corresponds to the following Frobenius eigenvalues 1 on $H^1_c(k^*_q; \overline{\mathbb{Q}}_m)$ and q on $H^2_c(k^*_q; \overline{\mathbb{Q}}_m)$. The map Fr is given by $Fr: z \mapsto z^q$.

Example 6.2. The case of $SL(2; \mathbb{R})$: The real form and K are determined by $\theta(A) = A^*$, the transpose of the inverse of A. Hence K(k) is given by $\begin{pmatrix} x & -y \\ y & x \end{pmatrix}$ where $x^2 + y^2 = 1$. Roots of $x^2 + 1$ are necessary to diagonalize K and this introduces a difference between fields \mathbb{F}_q such that $x^2 + 1$ splits into linear factors and fields for which this is not the case. We have an action of $SL(2; k_q)$ on \mathbb{P}^1 which can be described with fractional linear transformations. Hence K acts as follows on z, $\begin{pmatrix} x & -y \\ y & x \end{pmatrix} \cdot z = \frac{xz-y}{yz+x}$. When z = 0 we obtain the orbit $\{r = -\frac{y}{x} \mid x^2 + y^2 = 1, x \neq 0\} \cup \{\infty\}$. We have $r = \pm \frac{y}{\sqrt{1-y^2}}$ and $y = \pm \frac{r}{\sqrt{1+r^2}}$ in the algebraically closed field k_q . Therefore for any r such that $r^2 + 1 \neq 0$, we get a y and then an $x = \pm \sqrt{1-y^2}$. Hence the set of $r \in k_q$, the points in the orbit $\mathcal{O}_o(k_q)$ which are not ∞ , is given as the set $\{r \mid r^2 + 1 \neq 0\}$. We now compute the number of \mathbb{F}_q points (see the A_1 example in Introduction). There are two possibilities depending on the finite field \mathbb{F}_q : if $r^2 + 1 \neq 0$ in \mathbb{F}_q we obtain a contribution of q elements in $\mathcal{O}_o(\mathbb{F}_q)$. In the case when $r^2 + 1 = 0$ has two solutions, $\pm \sqrt{-1}$, we obtain q - 2 points from the possible values of r excluding these two roots, then taking into account the point ∞ we have a total of q - 1 points. These formulas corresponds to the following Frobenius eigenvalues, ± 1 on $H^1_c(\mathcal{O}_o(k); \overline{\mathbb{Q}}_m)$ and q on

 $H_c^2(\mathcal{O}_o(k_q); \overline{\mathbb{Q}}_m)$. The eigenvalue +1 of Frobenius acting on $H_c^1(\mathcal{O}_o(k); \overline{\mathbb{Q}}_m)$ then corresponds to the case when $x^2 + 1$ factors over \mathbb{F}_q . By considering $\mathbb{F}_p[\sqrt{-1}]$ when necessary, it is possible to assume that $x^2 + 1$ splits in \mathbb{F}_q . For example over \mathbb{F}_3 (q = 3) the equation $x^2 + 1 = 0$ has no roots and this is the reason that $x_1^2 + x_2^2 = 1$ contains 4 = q + 1 points, $\{(1,0), (2,0), (0,1), (0,2)\}$. However we can change this by simply considering $\mathbb{F}_{3^2} = \mathbb{F}_3[\sqrt{-1}]$ and then obtain q - 1 = 8 points for the new $q = 3^2$. Over \mathbb{F}_5 , the equation $x^2 + 1 = 0$ has two solutions x = 2, 3. In this case $x_1^2 + x_2^2 = 1$ contains 4 = q - 1 points, $\{(1,0), (0,1), (0,4)\}$.

By using the Lefschetz Fixed Point Theorem applied to the Frobenius map to count the number of \mathbb{F}_q points and that the number $|K(\mathbb{F}_q)|$ is given in p.75 of [5], we obtain the following:

Proposition 6.2. For any q, power of a prime $p \neq 2$ such that $x^2 + 1$ factors as product of linear terms, we have $|\check{\mathcal{O}}_o(\mathbb{F}_q)| = q^{r_1}p(q)$ with $r_1 = \dim(\check{K}) - \deg(p(q))$ where p(q) is given by

$$p(q) = (-1)^{l(w_*)} \sum_{w \in W^-} (-1)^{l(w)} q^{\eta(w)}.$$

Here W^- is defined by $W^- = \{ w \in W \mid w^{-1}(-\ldots -) = (-\ldots -) \}.$

Proof. The cohomology of $\check{\mathcal{O}}_o$ is given in terms of a chain complex

 $\cdots \to H^{s}(\check{\mathcal{Y}}_{s}, \check{\mathcal{Y}}_{s-1}; \mathbb{C}) \to H^{s+1}(\check{\mathcal{Y}}_{s+1}, \check{\mathcal{Y}}_{s}; \mathbb{C}) \to \cdots$

Take \mathcal{L} the trivial local system. Those w for which \mathcal{L}_w is trivial correspond to $w \in W^-$. These are the w which contribute to the Betti numbers. We now recall that from the Lefschetz fixed point formula for Fr the alternating sum is given by

$$\sum_{s} (-1)^{s} \operatorname{Tr}\left((Fr)_{*}|_{H^{s}_{c}(\check{\mathcal{O}}_{o}(k_{q}); \bar{\mathbb{Q}}_{m})} \right) = |\check{\mathcal{O}}_{o}(k_{q})|$$

By the Poincare duality, $H_c^{2\dim(\check{K})-s}(\check{\mathcal{O}}_o(k_q);\bar{\mathbb{Q}}_m)$ is the dual of $H^s(\check{\mathcal{O}}_o(k_q);\bar{\mathbb{Q}}_m)$. Then the alternating sum of the traces of Frobenius in cohomology is $(-1)^{l(w_*)}p(q) = \sum_{w \in W} (-1)^{l(w)}q^{\eta(w)}$. Since only elements in W^- contribute to the Betti numbers, the W in the sum can be replaced by W^- . Replacing cohomology with cohomology with proper supports amounts to replacing $q \to q^{-1}$ and multiplying by $q^{\dim(\check{K})}$ this previous expression. We write $\dim(\check{K}) = r_1 + \eta(w_*)$ and now $\sum_{w \in W} (-1)^{l(w)} q^{\eta(w)}$ gives rise to $q^{r_1} \sum_{w \in W} (-1)^{l(w)} q^{\eta(w_*)-\eta(w)}$. By Proposition 2.1 $(\eta(w_*w) = \eta(w_*) - \eta(w))$, we obtain $q^{r_1} \sum_{w \in W} (-1)^{l(w)} q^{\eta(w_*w)}$. Since $l(w_*w) = l(w_*) - l(w)$, our expression becomes $q^{r_1}(-1)^{l(w_*)} \sum_{w \in W} (-1)^{l(w_*w)} q^{\eta(w_*w)}$. This is $q^{r_1}p(q)$. Therefore the alternating sum of the traces of Fr in cohomology with proper supports is $q^{r_1}p(q)$.

Notation 6.3. We now consider several projections:

- We first express $p: G(\mathbb{C})/B(\mathbb{C}) \to \{*\}$, the projection to a point $\{*\}$ as a composition of the projection, $\pi_i: G(\mathbb{C})/B(\mathbb{C}) \to G(\mathbb{C})/P_i(\mathbb{C})$ and the projection to a point $p_i: G(\mathbb{C})/P_i(\mathbb{C}) \to \{*\}$ so that $p = p_i \circ \pi_i$.
- Denote p^o the restriction of p to the $K(\mathbb{C})$ -orbit \mathcal{O}_o . Similarly denote p_i^o the restriction to $\pi_i(\mathcal{O}_o)$, that is, $p_i^o = p_i|_{\pi_i(\mathcal{O}_o)}$ and finally, $\pi_i^o = \pi_i|_{\mathcal{O}_o}$ the restriction of π_i to \mathcal{O}_o .
- The fibration π_i has fibers E_x identifiable with \mathbb{P}^1 and the fibration π_i^o has fibers E_x^o identifiable with $\mathbb{C}^* = \mathbb{C} \setminus \{0\}$.

In the proof of the following proposition we use a sheaf-push-forward of the form $f_!$ (see chapter VII of [12]). Recall that this notation refers to a push-forward with compact supports. Moreover we consider derived functors (p.51 of [12]), obtained by considering injective resolutions (or soft resolutions) and then applying the push-forward to it. The reason for using this construction here is that the ordinary cohomology of an a space X is obtained by applying a push-forward $f: X \to \{*\}$ (to a point), to a constant sheaf. More precisely, we consider the derived functors $R^s f_*$ and apply them to a constant sheaf. If the push-forward is with proper supports, $R^s f_!$, then one obtains

cohomology with compact supports. These two notions of cohomology are related by Poincare duality when X is a smooth algebraic variety (Theorem 2.6 in p.263 of [12]).

Proposition 6.3. We have $H^k(K; \mathbb{Q}) = H^k(K/T; \mathbb{Q})$ for all k. Equivalently, for any nontrivial $K(\mathbb{C})$ -equivariant local system \mathcal{L} , we have $H^*(\mathcal{O}_o, \mathcal{L}) = 0$.

Proof. The fibration $s : K(\mathbb{C}) \to K(\mathbb{C})/T$ has finite fibers and $s_*(1)$ is a direct sum of all $K(\mathbb{C})$ -equivariant local systems on $K(\mathbb{C})/T$. Hence the rational cohomology of K is a direct sum of cohomology groups of K/T with twisted coefficients. To verify that $H^*(K/T; \mathbb{Q}) = H^*(K; \mathbb{Q})$ then it suffices to show that rational cohomology of K/T with twisted coefficients \mathcal{L} is zero.

The proof now becomes parallel, to the proof that $p_{\epsilon}(q) = 0$ when ϵ contains a positive sign $\epsilon_i = +$. In the proof of Proposition 3.1 a single arrow $e \Rightarrow s_i$ produces $p_{\epsilon}(q) = 0$. Here the non-triviality of a local system \mathcal{L} corresponds to $\epsilon_i = +$ for the sign $\epsilon = \epsilon(e, \mathcal{L})$.

We have $R^s p_!^o(\mathcal{L}) = H_c^s(\mathcal{O}_o; \mathcal{L})$, the cohomology with proper supports and with local coefficients, which can be written as $H_c^*(K/T; \mathcal{L})$. Similarly with the restriction p_i^o , the composition of functors $p_i^o \circ \pi_i^o = p^o$ gives rise to the spectral sequence (composition of functors spectral sequence as in p.343 of [4] or Theorem 7.15 in [12] in terms of derived categories) $R^k(p_i^o)_!(R^s(\pi_i^o)_!\mathcal{L}) \Rightarrow R^{k+s}p_!\mathcal{L}$. To show that $R^r p_!\mathcal{L} = 0$ for all r, it suffices to show that $R^s(\pi_i^o)_!\mathcal{L} = 0$ for at least one i and all s, s = 1, 2. For this it will be enough to compute the stalks over one single point x, of the sheaves $R^s(\pi_i^o)_!\mathcal{L})_x$ are given as $H_c^s(E_x^o;\mathcal{L}|_{E_x^o})$, that is, the cohomology with proper supports of the local system \mathcal{L} along a copy of $\mathbb{C}^* = \mathbb{C} \setminus \{0\}$. This has now reduced the argument to a calculation in the flag manifold for A_1 , since a fiber E_x of π_i can be identified with \mathbb{P}^1 and cohomology is along \mathbb{C}^* , a $K(\mathbb{C})$ -orbit for K = SO(3) or SU(2). Denote $\pi_i|_{E_x} = \pi_x$. Then we must compute $R^*(\pi_x^o)_!\mathcal{L}|_{E_x^o}$. To show that this is zero for some i. It now suffices that \mathcal{L} is non-trivial along the fiber $(\pi_i^o)^{-1}(x_e)$ for some i (again, corresponding to $\epsilon_i = +$ with $\epsilon = \epsilon(e, \mathcal{L})$). Since the rational cohomology of such a non-trivial local system along \mathbb{C}^* is zero, we have that $R^s(\pi_i^o)_!\mathcal{L} = 0$ as needed in our proof. \square

6.2. $|K(\mathbb{F}_q)|$, p(q) and the rational cohomology of K. Recall that the polynomial $|K(\mathbb{F}_q)|$ has a factorization $|K(\mathbb{F}_q)| = q^r \prod_{i=1}^g (q^{d_i} - 1)$ where d_1, \ldots, d_g are degrees of basic Weyl group invariant polynomials for K with $g = \operatorname{rank}(K)$ and r is the total number of positive roots associated with K(see [5]). Therefore the polynomial $|K(\mathbb{F}_q)|$ encodes the information that describes the cohomology ring of K. This cohomology ring is well-known; it is an exterior algebra with g generators of degrees $2d_i - 1$. Furthermore, if we write the exterior algebra as $H^*(K; \mathbb{Q}) = \Lambda(q^{d_1}x_1, \ldots, q^{d_g}x_g)$, we obtain a filtration of cohomology by the powers of q that result. This filtration can be seen to correspond to a filtration by Frobenius eigenvalues in etale cohomology of $K(k_q)$. We illustrate the relation between the polynomial $|K(\mathbb{F}_q)|$ and cohomology with the examples of A_3 and G_2 :

Example 6.4. In the case of type A_3 , we have K = SO(4) and $|SO(4; \mathbb{F}_q)| = q^2(q^2 - 1)(q^2 - 1)$, i.e. $d_1 = 2, d_2 = 2$ (since SO(4) and $SU(2) \times SU(2)$ have the same Lie algebra, and for SU(2) we have $d_1 = 2$ associated to the Casimir operator). We consider then the exterior algebra with generators $\{q^2x_1, q^2x_2\}$. From here one can write the rational cohomology of K, and even more, $\overline{\mathbb{Q}}_m$ the etale cohomology of $K(k_q)$ (with $m \neq 2$ a prime which is relatively prime to q),

$$\begin{cases} H^{0}(SO(4;k_{q});\mathbb{Q}_{m}) = \mathbb{Q}_{m}(q^{0}1) & : \text{ trace} = q^{0} \\ H^{3}(SO(4;k_{q});\bar{\mathbb{Q}}_{m}) = \bar{\mathbb{Q}}_{m}(q^{2}x_{1}) \oplus \bar{\mathbb{Q}}_{m}(q^{2}x_{2}) & : \text{ trace} = 2q^{2} \\ H^{6}(SO(4;k_{q});\bar{\mathbb{Q}}_{m}) = \bar{\mathbb{Q}}_{m}(q^{4}x_{1} \wedge x_{2}) & : \text{ trace} = q^{4} \end{cases}$$

The alternating sum of the traces of Frobenius eigenvalues in cohomology gives $p(q) = (q^2 - 1)^2$. If we consider cohomology with proper supports then we obtain $q^2(q^2 - 1)^2 = |SO(4; \mathbb{F}_q)|$. The generators of degree 3 in this example correspond to linear combinations $x_1 = [121] \pm [232]$, $x_2 = [321] \pm [123]$ in terms of the graph in Figure 4 and the product $x_1 \wedge x_2$ corresponds to the longest element $w_* = [123121]$. The graph in Figure 4 is derived from the blow-ups of the Toda lattice but it agrees with the graph of incidence numbers of G/B (by Theorem 3.6 or by p.529 of [7]). These representatives have eigenvalues of Frobenius q^2 , q^2 and q^4 respectively. In the case of G_2 (Example 2.11) we also have that the Lie algebra of K agrees with the Lie algebra of $SU(2) \times SU(2)$. Therefore, in spite of the fact that the structure of the polytopes is very different in A_3 and G_2 (i.e. different dimension, different number of vertices and different number of divisors), the polynomial $|K(\mathbb{F}_q)| = q^2(q^2 - 1)^2$.

In the following, we assume that $p \neq 2$ and $x^2 + 1$ factors over the field \mathbb{F}_q :

Theorem 6.5. The polynomial p(q) satisfies $p(q) = \tilde{p}(q)$, which is $q^{-r}|\check{K}(\mathbb{F}_q)|$ with $r = \dim(\check{K}) - \deg(p(q))$. Moreover p(q) factors as $p(q) = \prod_{i=1}^{g} (q^{d_i} - 1)$ where d_1, \ldots, d_g are degrees of basic Weyl group invariant polynomials for \check{K} of rank g. The polynomial p(q) is given by the following explicit formulas:

$$\begin{split} A_l: \ \breve{K} &= SO(l+1), \\ l \ even: \ p(q) &= (q^2-1)(q^4-1)\cdots(q^{l-2}-1)(q^l-1), \ g = l/2 \\ l \ odd: \ p(q) &= (q^2-1)(q^4-1)\cdots(q^{l-3}-1)(q^{l-1}-1)(q^g-1), \ g = (l+1)/2 \\ B_l: \ \breve{K} &= U(l), \\ p(q) &= (q-1)(q^2-1)(q^3-1)\cdots(q^l-1), \ g = l \\ C_l: \ \breve{K} &= SO(l) \times SO(l+1), \\ l \ even: \ p(q) &= (q^2-1)^2(q^4-1)^2\cdots(q^{l-2}-1)^2(q^l-1)(q^{l/2}-1), \ g = l \\ l \ odd: \ p(q) &= (q^2-1)^2(q^4-1)^2\cdots(q^{l-1}-1)^2(q^{(l+1)/2}-1), \ g = l \\ D_l: \ \breve{K} &= SO(l) \times SO(l), \\ l \ even: \ p(q) &= (q^2-1)^2(q^4-1)^2(q^6-1)^2\dots(q^{l-2}-1)^2(q^{l/2}-1)^2, \ g = l \\ l \ odd: \ p(q) &= (q^2-1)^2(q^4-1)^2(q^6-1)^2\dots(q^{l-1}-1)^2, \ g = l-1 \\ E_6: \ \mathrm{Lie}(\breve{K}) &= \mathfrak{sp}(4), \\ p(q) &= (q^2-1)(q^4-1)(q^6-1)(q^8-1), \ g = 4 \\ E_7: \ \mathrm{Lie}(\breve{K}) &= \mathfrak{su}(8), \\ p(q) &= (q^2-1)(q^4-1)(q^6-1)(q^8-1)(q^{10}-1)(q^{12}-1)(q^{14}-1)(q^8-1), \ g = 8 \\ F_4: \ \mathrm{Lie}(\breve{K}) &= \mathfrak{sp}(1) \times \mathfrak{sp}(3), \\ p(q) &= (q^2-1)^2(q^4-1)(q^6-1), \ g = 4 \\ G_2: \ \mathrm{Lie}(\breve{K}) &= \mathfrak{su}(2) \times \mathfrak{su}(2), \\ p(q) &= (q^2-1)^2, \ g = 2 \\ \end{split}$$

Proof. By Proposition 6.2, we have $q^{r_1}p(q) = |\check{\mathcal{O}}_o(\mathbb{F}_q)|$. Then by Proposition 6.3, $|\check{\mathcal{O}}_o(\mathbb{F}_q)| = |\check{K}(\mathbb{F}_q)|$ (hence $r = r_1$). By possibly extending the field \mathbb{F}_q as described in Remark 2.5, we have a factorization $|\check{K}(\mathbb{F}_q)| = q^r \prod_{i=1}^g (q^{d_i} - 1)$ (see p.75 of [5]). Moreover the polynomials $|K(\mathbb{F}_q)|$ are also listed in p.75 of [5]. The only groups K that occur for the real split semisimple Lie groups are such that by possibly replacing q with q^2 as in Remark 2.5, $K(\mathbb{F}_q)$ is of type A, B, C or D in the classification of finite Chevalley groups given in p.37 of [5]. From the polynomials $|K(\mathbb{F}_q)|$ one then obtains the polynomials p(q) by dividing by q^r . Note also that where the group K = U(n)appears, we are dealing with a Chevalley group of type A, i.e. $SL(n; \mathbb{F}_q)$, after reduction to positive characteristic and then taking the \mathbb{F}_q points. This is because SU(n) has complexification $SL(n; \mathbb{C})$. The remark applies to the case of a Lie algebra of type B_l above and E_7 (e.g. a maximal compact Lie subgroup for type C_l is U(l) and we need to use of the check `which exchanges the maximal compact subgroups of C and B). □

From here we obtain:

Proposition 6.4. The number $\eta(w_*) = \deg(p(q))$ satisfies $\eta(w_*) = d_1 + \cdots + d_l$. Moreover we have $\eta(w_*) = d$, the multiplicity of the singularity of the Painlevé divisor $\mathcal{D}_0 = \bigcup_{j=1}^l \mathcal{D}_j$ at the point p_o , for any semisimple Lie algebra not containing factors of type E or F. We have the following formulas

for $\eta(w_*)$. The number $\eta(w_*)$ is, in each case, the complex dimension of any Borel subalgebra of $\operatorname{Lie}(K(\mathbb{C}))$ (and of $\operatorname{Lie}(\check{K}(\mathbb{C}))$),

 $\begin{array}{l} A_l \colon \eta(w_*) = \frac{l(l+2)}{4} \ if \ l \ is \ even; \quad \eta(w_*) = \frac{(l+1)^2}{4} \ if \ l \ is \ odd, \\ B_l \ or \ C_l \colon \eta(w_*) = \frac{l(l+1)}{2}, \\ D_l \colon \eta(w_*) = \frac{l^2}{2} \ if \ l \ is \ even; \quad \eta(w_*) = \frac{l^2-1}{2} \ if \ l \ is \ odd, \\ E_l \colon \eta(w_*) = 20 \ if \ l = 6; \quad \eta(w_*) = 35 \ if \ l = 7; \quad \eta(w_*) = 64 \ if \ l = 8, \\ F_4 \colon \eta(w_*) = 14, \\ G_2 \colon \eta(w_*) = 4. \end{array}$

Proof. The explicit computation of $\eta(w_*)$ follows from Theorem 6.5 which expresses p(q) in terms of the order of certain Chevalley groups. Using Proposition 3.2 for any semisimple Lie algebras with no E or F factors, we obtain $\eta(w_*) = d$, the dimension of any Borel subalgebra of $\text{Lie}(K(\mathbb{C}))$. We also expect that $\eta(w_*) = d$ is true for all semisimple Lie algebra (Conjecture 3.3). \Box
