Abstract. Under certain conditions, we give an estimate from above on the number of differential equations of order  $r+1$  with prescribed regular singular points, prescribed exponents at singular points, and having a quasi-polynomial flag of solutions. The estimate is given in terms of a suitable weight subspace of the tensor power  $U(\mathfrak{n}_{-})^{\otimes (n-1)}$ , where *n* is the number of singular points in  $\mathbb C$  and  $U(\mathfrak{n}_-)$  is the enveloping algebra of the nilpotent subalgebra of  $\mathfrak{gl}_{r+1}$ .

Dedicated to Askold Khovanskii on the occasion of his  $60<sup>th</sup>$  birthday.

#### 1. Introduction

Consider the differential equation

<span id="page-0-0"></span>(1) 
$$
F(x) u''(x) + G(x) u'(x) + H(x) u(x) = 0,
$$

where  $F(x)$  is a polynomial of degree n, and  $G(x)$ ,  $H(x)$  are polynomials of degree not greater than  $n-1$ ,  $n-2$ , respectively. If  $F(x)$  has no multiple roots, then all singular points of the equation are regular singular. Write

(2) 
$$
F(x) = \prod_{s=1}^{n} (x - z_s), \qquad \frac{G(x)}{F(x)} = - \sum_{s=1}^{n} \frac{m_s}{x - z_s}
$$

for suitable complex numbers  $m_s$ ,  $z_s$ . Then 0 and  $m_s+1$  are exponents at  $z_s$  of equation [\(1\)](#page-0-0). If  $-l$  is one of the exponents at  $\infty$ , then the other is  $l-1-\sum_{s=1}^n m_s$ .

**Problem** ([\[Sz\]](#page-10-0), Ch. 6.8) Given polynomials  $F(x)$ ,  $G(x)$  as above and a non-negative integer l,

<sup>1</sup> Supported in part by RFFI grant 05-01-00922.

<sup>2</sup> Supported in part by NSF grant DMS-0244579.

- (a) find a polynomial  $H(x)$  of degree at most  $n-2$  such that equation [\(1\)](#page-0-0) has a polynomial solution of degree l ;
- (b) find the number of solutions to Problem (a).

If  $H(x)$ ,  $u(x)$  is a solution to Problem (a), then the corresponding equation [\(1\)](#page-0-0) is called a Lame equation and the polynomial  $u(x)$  is called a Lame function.

**Example.** Let  $F(x) = 1 - x^2$ ,  $G(x) = \alpha - \beta + (\alpha + \beta + 2)x$ . Then  $H = l(l + \alpha + \beta + 1)$ and the corresponding polynomial solution of degree  $l$ , normalized by the condition  $u(1) = \binom{l+\alpha}{l}$  $\binom{1}{l}$ , is called the Jacobi polynomial and denoted by  $P_l^{(\alpha,\beta)}$  $\mathcal{U}^{(\alpha,\beta)}(x).$ 

The following result is classical.

<span id="page-1-0"></span>Theorem 1.1 (Cf. [\[Sz\]](#page-10-0), Ch. 6.8, [\[St\]](#page-10-1)).

• Let  $u(x)$  be a polynomial solution of [\(1\)](#page-0-0) of degree l with roots  $t_1^0, \ldots, t_l^0$  of multiplicity one. Then  $\mathbf{t}^0 = (t_1^0, \ldots, t_l^0)$  is a critical point of the function

$$
\Phi_{l,n}(\boldsymbol{t};\boldsymbol{z};\boldsymbol{m})\;=\;\prod_{i=1}^l\prod_{s=1}^n(t_i-z_s)^{-m_s}\prod_{1\leq i
$$

where  $\bm{z} = (z_1, \ldots, z_n)$  and  $\bm{m} = (m_1, \ldots, m_n)$ .

• Let  $\mathbf{t}^0$  be a critical point of the function  $\Phi_{l,n}(\cdot;\mathbf{z};\mathbf{m})$ , then the polynomial  $u(x)$ of degree l with roots  $t_1^0, \ldots, t_l^0$  is a solution of [\(1\)](#page-0-0) with  $H(x) = (-F(x)u''(x) G(x)u'(x))/u(x)$  being a polynomial of degree at most  $n-2$ .

The function  $\Phi_{l,n}(\cdot;\mathbf{z};m)$  is called the master function. The master function is a symmetric function of the variables  $t_1, \ldots, t_l$ . Therefore, the symmetric group  $S_l$ naturally acts on the set of critical points of the master function by permuting the coordinates.

By Theorem [1.1,](#page-1-0) the  $S_l$ -orbits of critical points are in one-to-one correspondence with solution  $H(x)$ ,  $u(x)$  of Problem (a) such that  $u(x)$  has no multiple roots.

The following result is also classical.

**Theorem 1.2** ( Cf. [\[Sz\]](#page-10-0), Ch. 6.8, [\[H\]](#page-9-0), [\[St\]](#page-10-1) ). If  $z_1, \ldots, z_n$  are distinct real numbers and  $m_1, \ldots, m_n$  are negative numbers, then the number of solutions to Problem (a) is equal  $to \binom{l+n-2}{l}$  $\binom{i-2}{l}$ .

Under these conditions on z and m, the master function has exactly  $\binom{l+n-2}{l}$  $\binom{n-2}{l}$  S<sub>l</sub>-orbits of critical points, see [\[Sz\]](#page-10-0) and [\[V3\]](#page-10-2).

The number  $\binom{l+n-2}{l}$  $\binom{n-2}{l}$  has the following representation theoretical interpretation. The universal enveloping algebra  $U(\mathfrak{n}_-)$  of the nilpotent subalgebra  $\mathfrak{n}_- \subset \mathfrak{gl}_2$  is generated by one element  $e_{21}$  and is weighted by powers of the generator. The number  $\binom{l+n-2}{l}$  $\binom{n-2}{l}$  is the dimension of the weight l part of the tensor power  $U(\mathfrak{n}_-)^{\otimes (n-1)}$ .

The case of nonnegative integers  $m_1, \ldots, m_n$  is interesting for applications to the Bethe ansatz method in the Gaudin model. For a nonnegative integer  $m$ , let  $L_m$  be the  $m + 1$ -dimensional irreducible  $\mathfrak{sl}_2$ -module. If  $m_1, \ldots, m_n$  are nonnegative integers and  $m_{\infty} = \sum_{s=1}^{n} m_s - 2l$  is a nonnegative integer, then for any distinct  $z_1, \ldots, z_n$  the number of  $S_l$ -orbits of critical points of the master function function  $\Phi_{l,n}(\cdot;\mathbf{z};m)$  is not greater than the multiplicity of the  $\mathfrak{sl}_2$ -module  $L_{m_\infty}$  in the tensor product  $\otimes_{s=1}^n L_{m_s}$ . Moreover, for generic  $z_1, \ldots, z_n$ , the number of  $S_l$ -orbits is equal to that multiplicity, see [\[ScV\]](#page-10-3).

The goal of this paper is to generalize the formulated results. We consider linear differential equations of order  $r + 1$  with regular singular points only, located at  $z_1, \ldots, z_n, \infty$ , and having prescribed exponents at each of the singular points. We introduce the notion of a quasi-polynomial flag of solutions for such a differential equation. (For a second order differential equation, a quasi-polynomial flag is just a solution of the form  $y(x) \prod_{s=1}^{n} (x - z_s)^{\lambda_s}$  where  $y(x)$  is a polynomial and  $\lambda_1, \ldots, \lambda_n$  are some complex numbers.) We prove two facts:

- Differential equations with a quasi-polynomial flag, prescribed singular points and exponents are in one-to-one correspondence with suitable orbits of critical points of some  $\mathfrak{gl}_{r+1}$ -master function.
- Under explicit generic conditions on exponents (they must be *separated*), we show that the number of orbits of critical points of the corresponding master function is not greater than the dimension of a suitable weight subspace of  $U(\mathfrak{n}_-)^{\otimes (n-1)}$ , where  $\mathfrak{n}_-$  is the nilpotent subalgebra of  $\mathfrak{gl}_{r+1}$ .

The proofs are based on results from [\[MV2,](#page-9-1) [BMV\]](#page-9-2).

This paper was motivated by discussions with B. Shapiro of his preprint [\[BBS\]](#page-9-3) in which another generalization of Problems (a) and (b) is introduced for differential equations of order  $r + 1$ . The authors thank B. Shapiro for useful discussions of his preprint.

## 2. CRITICAL POINTS OF  $\mathfrak{gl}_{r+1}$ -MASTER FUNCTIONS

<span id="page-2-0"></span>2.1. Lie algebra  $\mathfrak{gl}_{r+1}$ . Consider the Lie algebra  $\mathfrak{gl}_{r+1}$  with standard generators  $e_{a,b}$ ,  $a, b = 1, \ldots, r + 1$ , and Cartan decomposition  $\mathfrak{gl}_{r+1} = \mathfrak{n}_- \oplus \mathfrak{h} \oplus \mathfrak{n}_+,$ 

$$
\mathfrak{n}_- = \oplus_{a > b} \mathbb{C} \cdot e_{a,b} \ , \qquad \mathfrak{h} \ = \oplus_{a=1}^{r+1} \mathbb{C} \cdot e_{a,a} \ , \qquad \mathfrak{n}_+ = \oplus_{a < b} \mathbb{C} \cdot e_{a,b} \ .
$$

Set  $h_a = e_{a,a} - e_{a+1,a+1}$  for  $a = 1, ..., r$ . Let  $e_{1,1}^*, ..., e_{r+1,r+1}^* \in \mathfrak{h}^*$  be the basis dual to the basis  $e_{1,1},\ldots,e_{r+1,r+1}\in\mathfrak{h}$ . Set  $\alpha_a=e_{a,a}^*-e_{a+1,a+1}^*$  for  $a=1,\ldots,r$ . Fix the scalar product on  $\mathfrak{h}^*$  such that  $(e^*_{a,a}, e^*_{b,b}) = \delta_{a,b}$ .

Let  $U(\mathfrak{n}_-)$  be the universal enveloping algebra of  $\mathfrak{n}_-$ ,

$$
U(\mathfrak{n}_-) = \bigoplus_{\mathbf{l} \in \mathbb{Z}_{\geq 0}^r} U(\mathfrak{n}_-)[\mathbf{l}] \ ,
$$

where for  $\mathbf{l} = (l_1, \ldots, l_r)$ , the space  $U(\mathfrak{n}_-)[\mathbf{l}]$  consists of elements f such that

$$
[f,h] = \langle h \, , \, \sum_{i=1}^r l_i \alpha_i \rangle f \, .
$$

The element  $\prod_i e_{a_i,b_i}$  with  $a_i > b_i$  belongs to the graded subspace  $U(\mathfrak{n}_-) [l]$ , where  $\bm{l} = \sum_i \bm{l}_i \; \text{with}$ 

 $l_i = (0, 0, \ldots, 0, 1_h, 1_{h+1}, \ldots, 1_{a-1}, 0, 0, \ldots, 0)$ .

Choose an order on the set of elements  $e_{a,b}$  with  $r + 1 \ge a > b \ge 1$ . Then the ordered products  $\prod_{a>b} e_{a,b}^{n_{a,b}}$  form a graded basis of  $U(\mathfrak{n}_-)$ .

The grading of  $U(\mathfrak{n}_-)$  induces the grading of  $U(\mathfrak{n}_-)^{\otimes k}$  for any positive integer k,

$$
U(\mathfrak{n}_-)^{\otimes k} = \bigoplus_l U(\mathfrak{n}_-)^{\otimes k}[l] .
$$

Denote

$$
d(k,l) = \dim U(\mathfrak{n}_-)^{\otimes k}[l].
$$

For a weight  $\Lambda \in \mathfrak{h}^*$ , denote by  $L_{\Lambda}$  the irreducible  $\mathfrak{gl}_{r+1}$ -module with highest weight Λ. Let

> $\Lambda = (\Lambda_1, \ldots, \Lambda_n)$ , ∗ ,

be a collection of weights and  $\mathbf{l} = (l_1, \ldots, l_r)$  a collection of nonnegative integers. Let

$$
L_{\mathbf{\Lambda}} = L_{\Lambda_1} \otimes \cdots \otimes L_{\Lambda_n}
$$

be the tensor product of irreducible  $\frak{gl}_{r+1}$ -modules. Let  $L_{\mathbf{\Lambda}} = \oplus_{\bm{l} \in \mathbb{Z}_{\geq 0}^r} L_{\mathbf{\Lambda}}[\bm{l}]$  be its weight decomposition, where  $L_{\mathbf{\Lambda}}[(l_1,\ldots,l_r)]$  is the subspace of vectors of weight  $\sum_{s=1}^n \Lambda_s$ decomposition, where  $L_{\mathbf{\Lambda}}[(l_1, \ldots, l_r)]$  is the subspace of vectors of weight  $\sum_{s=1}^n \Lambda_s - \sum_{i=1}^r l_i \alpha_i$ . Let  $\text{Sing } L_{\mathbf{\Lambda}}[l] \subset L_{\mathbf{\Lambda}}[l]$  be the subspace of singular vectors, i.e. the subspace of vectors annihilated by  $\mathfrak{n}_+$ . Denote

$$
\delta(\Lambda, l) = \dim \, \mathrm{Sing} \, L_{\Lambda}[l] \; .
$$

It is well-known that for given l and a generic set of weights  $\Lambda$ , we have

$$
d(n-1,\boldsymbol{l}) = \delta(\boldsymbol{\Lambda},\boldsymbol{l}) .
$$

For given  $\Lambda$  and  $l$ , introduce the weight

$$
\Lambda_{\infty} = \sum_{s=1}^{n} \Lambda_s - \sum_{i=1}^{r} l_i \alpha_i \in \mathfrak{h}^*
$$

and the sequences of numbers  $m_1, \ldots, m_{r+1}, m_\infty$ , where

$$
\mathbf{m}_s = \{m_{s,1},\ldots,m_{s,r+1}\}\qquad \text{and} \qquad m_{s,i} = \langle \Lambda_s, e_{i,i} \rangle.
$$

Having sequences  $m_1, \ldots, m_{r+1}, m_\infty$ , we can recover  $\Lambda$  and l as follows:

<span id="page-3-0"></span>(3) 
$$
\Lambda_s = \sum_{i=1}^{r+1} m_{s,i} e_{i,i}^*
$$
 and  $\sum_{i=1}^{r} l_i \alpha_i = \sum_{s=1}^{n} \Lambda_s - \Lambda_\infty$ .

We say that the set of sequences  $m_1, \ldots, m_{r+1}, m_\infty$  of complex numbers is *admissible*, if all of the numbers  $\mathbf{l} = (l_1, \ldots, l_r)$ , defined by [\(3\)](#page-3-0), are nonnegative integers.

2.2. **Master functions.** Let  $\mathbf{z} = (z_1, \ldots, z_n) \in \mathbb{C}^n$  be a point with distinct coordinates. Let

$$
\Lambda = (\Lambda_1, \ldots, \Lambda_n) , \qquad \Lambda_s \in \mathfrak{h}^* ,
$$

be a collection of  $\mathfrak{gl}_{r+1}$ -weights and  $\mathbf{l} = (l_1, \ldots, l_r)$  a collection of nonnegative integers. Set  $l = l_1 + \cdots + l_r$ . Introduce a function of l variables

$$
\boldsymbol{t} = (t_1^{(1)}, \dots, t_{l_1}^{(1)}, \dots, t_1^{(r)}, \dots, t_{l_r}^{(r)})
$$

by the formula

<span id="page-4-1"></span>
$$
(4) \quad \Phi(t; z; \Lambda; l) =
$$
\n
$$
= \prod_{i=1}^{r} \prod_{j=1}^{l_i} \prod_{s=1}^{n} (t_j^{(i)} - z_s)^{-(\Lambda_s, \alpha_i)} \prod_{i=1}^{r} \prod_{1 \leq j < s \leq l_i} (t_j^{(i)} - t_s^{(i)})^2 \prod_{i=1}^{r-1} \prod_{j=1}^{l_i} \prod_{k=1}^{l_{i+1}} (t_j^{(i)} - t_k^{(j+1)})^{-1} \; .
$$

The function  $\Phi$  is a (multi-valued) function of t, depending on parameters  $\mathbf{z}, \mathbf{\Lambda}$ . The function is called the master function.

The master functions arise in the hypergeometric solutions of the KZ equations [?, [V1\]](#page-10-4) and in the Bethe ansatz method for the Gaudin model [\[RV,](#page-9-4) [ScV,](#page-10-3) [MV1,](#page-9-5) [MV2,](#page-9-1) [MV3,](#page-9-6) [V2,](#page-10-5) [MTV\]](#page-9-7).

The product of symmetric groups

$$
S_{\boldsymbol{l}} = S_{l_1} \times \cdots \times S_{l_r}
$$

acts on variables  $t$  by permuting the coordinates with the same upper index. The master function is  $S_l$ -invariant.

A point **t** with complex coordinates is called a critical point of  $\Phi(\cdot; z; \Lambda; l)$  if the following system of  $l$  equations is satisfied

<span id="page-4-0"></span>(5)  

$$
\sum_{s=1}^{n} \frac{(\Lambda_s, \alpha_1)}{t_j^{(1)} - z_s} - \sum_{s=1, s \neq j}^{l_1} \frac{2}{t_j^{(1)} - t_s^{(1)}} + \sum_{s=1}^{l_2} \frac{1}{t_j^{(1)} - t_s^{(2)}} = 0,
$$
  

$$
\sum_{s=1}^{n} \frac{(\Lambda_s, \alpha_i)}{t_j^{(i)} - z_s} - \sum_{s=1, s \neq j}^{l_i} \frac{2}{t_j^{(i)} - t_s^{(i)}} + \sum_{s=1}^{l_{i-1}} \frac{1}{t_j^{(i)} - t_s^{(i-1)}} + \sum_{s=1}^{l_{i+1}} \frac{1}{t_j^{(i)} - t_s^{(i+1)}} = 0,
$$
  

$$
\sum_{s=1}^{n} \frac{(\Lambda_s, \alpha_r)}{t_j^{(r)} - z_s} - \sum_{s=1, s \neq j}^{l_r} \frac{2}{t_j^{(r)} - t_s^{(r)}} + \sum_{s=1}^{l_{r-1}} \frac{1}{t_j^{(r)} - t_s^{(r-1)}} = 0,
$$

where  $j = 1, \ldots, l_1$  in the first group of equations,  $i = 2, \ldots, r - 1$  and  $j = 1, \ldots, l_i$  in the second group of equations,  $j = 1, \ldots, l_r$  in the last group of equations.

In other words, a point  $t$  is a critical point if

$$
\left(\Phi^{-1}\frac{\partial \Phi}{\partial t_j^{(i)}}\right)(\boldsymbol{t};\boldsymbol{z};\boldsymbol{\Lambda};\boldsymbol{l}) = 0 , \qquad i=1,\ldots,r, \; j=1,\ldots l_i \; .
$$

In the Gaudin model, equations [\(5\)](#page-4-0) are called the Bethe ansatz equations.

The set of critical points is  $S_l$ -invariant.

2.3. The case of isolated critical points. We say that the pair  $\Lambda, l$  is separating if

$$
(2\Lambda_{\infty} + \sum_{i=1}^{r} c_i \alpha_i, \sum_{i=1}^{r} c_i \alpha_i) + 2\sum_{i=1}^{r} c_i \neq 0
$$

<span id="page-5-0"></span>for all sets of integers  $\{c_1, \ldots, c_r\}$  such that  $0 \leq c_i \leq l_i, \sum_i c_i \neq 0$ .

For example, if  $\Lambda_{\infty}$  is dominant integral, then  $\Lambda, l$  is separating.

**Lemma 2.1** (Theorem 16 [\[ScV\]](#page-10-3), Lemma 2.1 [\[MV2\]](#page-9-1)). If the pair  $\Lambda$ , **l** is separating, then the set of critical points of the master function  $\Phi(\cdot; z; \Lambda; l)$  is finite.

<span id="page-5-2"></span>By Lemma [2.1,](#page-5-0) for given l and generic  $\Lambda$ , the master function  $\Phi(\cdot; z; \Lambda; l)$  has finitely many critical points.

**Theorem 2.2.** Assume that the pair  $\Lambda$ , **l** is separating, then the number of  $S_l$ -orbits of critical points counted with multiplicities is not greater than  $d(n-1, l)$ .

The multiplicity of a critical point  $t$  is the multiplicity of  $t$  as a solution of system [\(5\)](#page-4-0).

*Proof.* It is shown in [\[BMV\]](#page-9-2) that, if  $\Lambda_1, \ldots, \Lambda_n, \Lambda_\infty$  is a collection of dominant integral weights, then the number of  $S_l$ -orbits of critical points counted with multiplicities is not greater than  $\delta(\Lambda, l)$ . Together with equality  $d(n-1, l) = d(\Lambda, l)$  for generic  $\Lambda$ , this proves the theorem.  $\Box$ 

#### 3. Differential operators with quasi-polynomial flags of solutions

3.1. Fundamental differential operator. For the  $S_l$ -orbit of a critical point  $t$  of the master function  $\Phi(\cdot; z; \Lambda; l)$ , define the tuple  $y^t = (y_1, \ldots, y_r)$  of polynomials in variable x,

$$
y_i(x) = \prod_{j=1}^{l_i} (x - t_j^{(i)}), \qquad i = 1, ..., r.
$$

Since **t** is a critical point, all fractions in [\(5\)](#page-4-0) are well-defined. Therefore, the tuple  $y^t$ has the following properties:

- <span id="page-5-1"></span> $(6)$  Every polynomial  $y_i$  has no multiple roots.
- (7) Every pair of polynomials  $y_i$  and  $y_{i+1}$  has no common roots.
- (8) For every  $i = 1, ..., r$  and  $s = 1, ..., n$ , if  $m_{s,i} m_{s,i+1} \neq 0$ , then  $y_i(z_s) \neq 0$ .

A tuple of monic polynomials  $(y_1, \ldots, y_r)$  with properties  $(6)-(8)$  $(6)-(8)$  will be called off-diagonal.

<span id="page-6-0"></span>Define quasi-polynomials  $T_1, \ldots, T_{r+1}$  in x by the formula

(9) 
$$
T_i(x) = \prod_{s=1}^n (x - z_s)^{-m_{s,i}}.
$$

Consider the linear differential operator of order  $r + 1$ ,

$$
D_{\mathbf{t}} = \left(\frac{d}{dx} - \ln'\left(\frac{T_{r+1}}{y_r}\right)\right) \left(\frac{d}{dx} - \ln'\left(\frac{y_r T_r}{y_{r-1}}\right)\right) \dots \left(\frac{d}{dx} - \ln'\left(\frac{y_2 T_2}{y_1}\right)\right) \left(\frac{d}{dx} - \ln'(y_1 T_1)\right)
$$

<span id="page-6-1"></span>where  $\ln'(f)$  denotes  $\left(\frac{df}{dx}\right)/f$  for any f. We say that  $D_t$  is the fundamental operator of the critical point  $t$ .

**Theorem 3.1.** Assume that the pair  $\Lambda$ , **l** is separating. Then

(i) All singular points of  $D_t$  are regular and lie in  $z_1, \ldots, z_n, \infty$ . The exponents of  $D_t$  at  $z_s$  are

 $-m_{s,1}, -m_{s,2}+1, \ldots, -m_{s,r+1}+r$ 

for  $s = 1, \ldots, n$ , and the exponents of  $D_t$  at  $\infty$  are

$$
m_{\infty,1}
$$
,  $m_{\infty,2}-1$ , ...,  $m_{\infty,r+1}-r$ .

(ii) The differential equation  $D_t u = 0$  has solutions  $u_1, \ldots, u_{r+1}$  such that

$$
u_1 = y_1 T_1
$$

and for  $i = 2, \ldots, r + 1$  we have

$$
Wr (u_1, \ldots, u_i) = y_i T_i T_{i-1} \ldots T_1
$$

where  $Wr(u_1, \ldots, u_i)$  denotes the Wronskian of  $u_1, \ldots, u_i$  and  $y_{r+1} = 1$ .

*Proof.* Part (ii) follows from the presentation of  $D_t$  as a product. To prove part (i) consider the operator  $\tilde{D}_t = T_1^{-1} \cdot D_t \cdot T_1$ , the conjugate of  $D_t$  by the operator of multiplication by  $T_1$ . Then

$$
\tilde{D}_{t} = \left(\frac{d}{dx} - \ln'\left(\frac{T_{r+1}}{y_{r}T_{1}}\right)\right) \left(\frac{d}{dx} - \ln'\left(\frac{y_{r}T_{r}}{y_{r-1}T_{1}}\right)\right) \dots \left(\frac{d}{dx} - \ln'\left(\frac{y_{2}T_{2}}{y_{1}T_{1}}\right)\right) \left(\frac{d}{dx} - \ln'(y_{1})\right) \, .
$$

It is enough to show that

- (iii) All singular points of  $\tilde{D}_t$  are regular and lie in  $\{z_1, \ldots, z_n, \infty\}$ .
- (iv) The exponents of  $\tilde{D}_t$  at  $z_s$  are

$$
0, m_{s,1} - m_{s,2} + 1, \ldots, m_{s,1} - m_{s,r+1} + r
$$
,

for  $s = 1, \ldots, n$ , and the exponents of  $\tilde{D}_t$  at  $\infty$  are

 $-l_1$ ,  $-m_{\infty,1}+m_{\infty,2}-1-l_1$ ,  $\ldots$ ,  $-m_{\infty,1}+m_{\infty,r+1}-r-l_1$ .

If all highest weights in the collection  $\Lambda_1, \ldots, \Lambda_n, \Lambda_\infty$  are integral dominant, then statements (iii-iv) are proved in [\[MV2\]](#page-9-1), Section 5. Hence statements (iii-iv) hold for arbitrary separating  $\Lambda_1, \ldots, \Lambda_n$ ,  $\bm{l}$ .

3.2. Quasi-polynomial flags. Let  $\boldsymbol{z} = (z_1, \ldots, z_n) \in \mathbb{C}^n$  be a point with distinct coordinates. Let  $m_1, \ldots, m_{r+1}, m_\infty$  be an admissible set of sequences of complex numbers as in Section [2.1.](#page-2-0) Let

$$
D = \frac{d^{r+1}}{dx^{r+1}} + A_1(x)\frac{d^r}{dx^r} + \ldots + A_r(x)\frac{d}{dx} + A_{r+1}(x)
$$

be a differential operator with rational coefficients.

We say that D is associated with  $z, m_1, \ldots, m_{r+1}, m_\infty$ , if

- All singular points of D are regular and lie in  $z_1, \ldots, z_n, \infty$ .
- The exponents of D at  $z_s$  are  $-m_{s,1}$ ,  $-m_{s,2}+1$ ,  $\ldots$ ,  $-m_{s,r+1}+r$  for  $s=1,\ldots,n$ .
- The exponents of D at  $\infty$  are  $m_{\infty,1}$ ,  $m_{\infty,2}-1$ , ...,  $m_{\infty,r+1}-r$ .

Define quasi-polynomials  $T_1, \ldots, T_{r+1}$  in x by formula [\(9\)](#page-6-0).

We say that an operator D, associated with  $z, m_1, \ldots, m_{r+1}, m_\infty$ , has a quasipolynomial flag, if there exists a tuple  $y = (y_1, \ldots, y_r)$  of monic polynomials in x, such that

- (i) For  $i = 1, ..., r$ , deg  $y_i = l_i$ .
- (ii) The tuple  $y$  is off-diagonal in the sense of [\(6\)](#page-5-1)-[\(8\)](#page-5-1).
- (iii) The differential equation  $D u = 0$  has solutions  $u_1, \ldots, u_{r+1}$  such that

$$
u_1 = y_1 T_1
$$

and for  $i = 2, \ldots, r + 1$  we have

$$
Wr (u_1, \ldots, u_i) = y_i T_i T_{i-1} \ldots T_1,
$$

where  $y_{r+1} = 1$ .

**Proposition 3.2.** An operator D, associated with  $z, m_1, \ldots, m_{r+1}, m_\infty$ , has a quasipolynomial flag if and only there exists a tuple  $y = (y_1, \ldots, y_r)$  of monic polynomials in x with properties (i-ii) and

(iv) The differential operator D can be presented in the form

$$
D = \left(\frac{d}{dx} - \ln'\left(\frac{T_{r+1}}{y_r}\right)\right) \left(\frac{d}{dx} - \ln'\left(\frac{y_r T_r}{y_{r-1}}\right)\right) \dots \left(\frac{d}{dx} - \ln'\left(\frac{y_2 T_2}{y_1}\right)\right) \left(\frac{d}{dx} - \ln'(y_1 T_1)\right).
$$

*Proof.* The equivalence of (iii) and (iv) follows from the next lemma.

**Lemma 3.3.** Let  $u_1, \ldots, u_{r+1}$  be any functions such that

$$
Wr (u_1, \ldots, u_i) = y_i T_i T_{i-1} \ldots T_1,
$$

for  $i = 1, \ldots, r + 1$ . Then  $u_1, \ldots, u_{r+1}$  form a basis of the space of solutions of the equation  $Du = 0$  with

$$
D = \left(\frac{d}{dx} - \ln'\left(\frac{T_{r+1}}{y_r}\right)\right) \left(\frac{d}{dx} - \ln'\left(\frac{y_r T_r}{y_{r-1}}\right)\right) \dots \left(\frac{d}{dx} - \ln'\left(\frac{y_2 T_2}{y_1}\right)\right) \left(\frac{d}{dx} - \ln'(y_1 T_1)\right).
$$

*Proof.* It is enough to prove that  $D u_i = 0$  for  $i = 1, ..., r + 1$ . By induction on i, we obtain that

$$
\left(\frac{d}{dx} - \ln'(\frac{y_i T_i}{y_{i-1}})\right) \dots \left(\frac{d}{dx} - \ln'(\frac{y_2 T_2}{y_1})\right) \left(\frac{d}{dx} - \ln'(y_1 T_1)\right) u = \frac{W(u_1, \dots, u_i, u)}{y_i T_i T_{i-1} \dots T_1}
$$

from which the statement follows.  $\Box$ 

Examples of differential operators with quasi-polynomial flags are given by Theorem [3.1.](#page-6-1) If t is a critical point of the master function  $\Phi(\cdot; z; \Lambda; l)$ , then by Theorem [3.1,](#page-6-1) the fundamental differential operator  $D_t$  is associated with  $z, m_1, \ldots, m_{r+1}, m_\infty$  and has a quasi-polynomial flag.

Having  $\boldsymbol{z}, \, \boldsymbol{m}_1, \ldots, \boldsymbol{m}_{r+1}, \boldsymbol{m}_{\infty}$ , define  $\boldsymbol{\Lambda}, \, \boldsymbol{l}$  by [\(3\)](#page-3-0) and the master function  $\Phi(\cdot; \boldsymbol{z}; \boldsymbol{\Lambda}; \boldsymbol{l})$ by  $(4)$ .

<span id="page-8-0"></span>Having a tuple 
$$
\mathbf{y} = (y_1, ..., y_r), y_i(x) = \prod_{j=1}^{l_i} (x - t_j^{(i)})
$$
, denote by

(10) 
$$
\boldsymbol{t} = (t_1^{(1)}, \ldots, t_{l_1}^{(1)}, \ldots, t_1^{(r)}, \ldots, t_{l_r}^{(r)})
$$

<span id="page-8-1"></span>a point in  $\mathbb{C}^l$ , whose coordinates are roots of the polynomials of  $\bm{y}$ . The tuple  $\bm{y}$  uniquely determines the  $S_l$ -orbit of  $t$ .

**Theorem 3.4.** Assume that an operator D is associated with  $z, m_1, \ldots, m_{r+1}, m_\infty$ and has a quasi-polynomial flag. Let  $y$  be the corresponding tuple of polynomials. Then the point **t**, introduced in [\(10\)](#page-8-0), is a critical point of the master function  $\Phi(\cdot; z; \Lambda; l)$ .

*Proof.* Let  $u_1, \ldots, u_{r+1}$  be the set of solutions of the differential equation  $D u = 0$  giving the quasi-polynomial flag. Introduce the functions  $\tilde{y}_1, \ldots, \tilde{y}_r$  by the formulas  $u_2 = \tilde{y}_1 T_1$ and for  $i = 2, \ldots, r$ ,

 $\tilde{y}_i T_i T_{i-1} \dots T_1 = \text{Wr}(u_1, \dots, u_{i-1}, u_{i+1})$ .

The functions  $\tilde{y}_1, \ldots, \tilde{y}_r$  are multi-valued functions.

• Singularities of all branches of all of these functions lie in  $z_1, \ldots, z_n$ .

It follows from the Wronskian identities of [\[MV2\]](#page-9-1), that

• 
$$
\operatorname{Wr}(\tilde{y}_1, y_1) = \frac{T_2}{T_1} y_2
$$
,  $\operatorname{Wr}(\tilde{y}_r, y_r) = \frac{T_{r+1}}{T_r} y_{r-1}$ ,  $\operatorname{Wr}(\tilde{y}_i, y_i) = \frac{T_{i+1}}{T_i} y_{i-1} y_{i+1}$ 

 $\Box$ 

for  $i = 2, \ldots, r - 1$ . These two properties of functions  $\tilde{y}_1, \ldots, \tilde{y}_r$  imply equations [\(5\)](#page-4-0) for roots of polynomials  $y_1, \ldots, y_r$ , see [\[MV2\]](#page-9-1). This shows that the point  $\boldsymbol{t}$  is a critical point.  $\Box$ 

The correspondence between critical points and differential operators with quasipolynomial flags is reflexive. If t is a critical point of the master function  $\Phi(\cdot; z; \Lambda; l)$ , which corresponds by Theorem [3.4](#page-8-1) to the differential operator  $D$ , then  $D$  is the fundamental differential operator of the critical point  $t$ .

3.3. Conclusion. Let  $\boldsymbol{z} = (z_1, \ldots, z_n) \in \mathbb{C}^n$  be a point with distinct coordinates. Let  $m_1, \ldots, m_{r+1}, m_\infty$  be an admissible set of sequences of complex numbers as in Section [2.1.](#page-2-0) Define  $\Lambda_1, \ldots, \Lambda_n, \Lambda_\infty$ , *l* by [\(3\)](#page-3-0). Assume that *l* is fixed and  $\Lambda_1, \ldots, \Lambda_n$  are separating (that is generic). Then the number of differential operators  $D$ , associated with  $z, m_1, \ldots, m_{r+1}, m_\infty$  and having a quasi-polynomial flag, is not greater than  $d(n-1, l)$ , see Theorems [2.2](#page-5-2) and [3.4.](#page-8-1)

It is interesting to note that if  $\Lambda_1, \ldots, \Lambda_n, \Lambda_\infty$ , are dominant integral, then the number of differential operators D, associated with  $z, m_1, \ldots, m_{r+1}, m_\infty$  and having a quasipolynomial flag, is not greater than the multiplicity  $\delta(\Lambda, l)$ , which could be a smaller number. See Theorem [3.4](#page-8-1) and description in  $\vert \text{MV2} \vert$  of the critical points of the corresponding master functions.
