

A note on Saleh's paper 'Almost continuity implies closure continuity'*

Julian DONTCHEV and Takashi NOIRI

Recently, Saleh [3] claimed to have solved 'a long standing open question' in Topology; namely, he proved that every almost continuous function is closure continuous (= θ -continuous). Unfortunately, this problem was settled long time ago and even a better result is known. Consider the following implications:

Cont. \Rightarrow Almost cont. \Rightarrow Almost α -cont. \Rightarrow η -cont. \Rightarrow θ -cont. \Rightarrow Weakly cont.

The first two implications are trivial. In [2], the second author showed that every almost α -continuous function is η -continuous. In [1], Dickman, Porter and Rubin proved that every η -continuous is θ -continuous and hence weakly continuous.

Although θ -continuous functions behave, in general, nicely, they may cause some unexpected problems. For example, if $f: X \rightarrow Y$ is θ -continuous, then $f: X \rightarrow f(X)$ is not necessarily θ -continuous. Also, the set of all points of continuity of $f: X \rightarrow Y$ may be dense in X and f may not be weakly continuous in either of those points. We show that with the following example:

Example. Consider the classical Dirichlet function $f: (\mathbb{R}, \tau_d) \rightarrow (\mathbb{R}, \tau_d)$, where \mathbb{R} is the real line with the density topology τ_d :

$$f(x) = \begin{cases} 1, & x \in \mathbb{Q}, \\ 0, & \text{otherwise.} \end{cases}$$

It is easily observed that f is continuous at every irrational point (furthermore, \mathbb{P} , the set of all irrationals is dense in the density topology). On the other hand f is not weakly continuous (and hence not θ -continuous) at any irrational point.
