

# A relationship between rational and multi-soliton solutions of the BKP hierarchy

J. J. C. Nimmo\*      A. Yu. Orlov†

November 7, 2018

## Abstract

We consider a special class of solutions of the BKP hierarchy which we call  $\tau$ -functions of hypergeometric type. These are series in Schur  $Q$ -functions over partitions, with coefficients parameterised by a function of one variable  $\xi$ , where the quantities  $\xi(k)$ ,  $k \in \mathbb{Z}^+$ , are integrals of motion of the BKP hierarchy. We show that this solution is, at the same time, a infinite soliton solution of a dual BKP hierarchy, where the variables  $\xi(k)$  are now related to BKP higher times. In particular, rational solutions of the BKP hierarchy are related to (finite) multi-soliton solution of the dual BKP hierarchy. The momenta of the solitons are given by the parts of partitions in the Schur  $Q$ -function expansion of the  $\tau$ -function of hypergeometric type. We also show that the KdV and the NLS soliton  $\tau$ -functions coincide the BKP  $\tau$ -functions of hypergeometric type, evaluated at special point of BKP higher time; the variables  $\xi$  (which are BKP integrals of motions) being related to KdV and NLS higher times.

## 1 Introduction

The BKP hierarchy was introduced in [1, 2] as a particular reduction of the KP hierarchy of integrable equations [1, 7]. Like the well-known KP hierarchy, the BKP hierarchy possesses multi-soliton and rational solutions. In [3, 4], the role of projective Schur functions ( $Q$ -functions) [6] in obtaining rational solutions of the BKP hierarchy was explained. In fact, the  $Q$ -functions are polynomial  $\tau$ -function solutions of the BKP hierarchy Hirota equations and these are connected to the rational solutions through a change of dependent variables.

In [9], certain hypergeometric series in  $Q$ -functions (see (85) below) were shown to be  $\tau$ -functions of the BKP hierarchy. These  $\tau$ -functions are series of the form

$$\tau(\mathbf{t}_o, \xi, \mathbf{t}_o^*) = \sum_{\lambda \in \text{DP}} e^{\sum_{i=1}^{\infty} \xi_{\lambda_i}} Q_{\lambda}(\frac{1}{2}\mathbf{t}_o) Q_{\lambda}(\frac{1}{2}\mathbf{t}_o^*), \quad (1)$$

where  $\xi = \{\xi_m : m = 1, 2, \dots\}$  are arbitrary parameters,  $\xi_0 = 0$ ,  $Q_{\lambda}$  denote projective Schur function, and the sum is over the set DP of all partitions  $\lambda = (\lambda_1, \lambda_2, \dots, \lambda_k)$  with distinct parts  $\lambda_1 > \lambda_2 > \dots > \lambda_k \geq 0$ . Considered as a function of the variables  $\mathbf{t}_o = (t_1, t_3, \dots)$ , series (1) is a BKP  $\tau$ -function, where the set  $\mathbf{t}_o$  are higher BKP times. The second set of parameters  $\mathbf{t}_o^* = (t_1^*, t_3^*, \dots)$  give the evolution in a second BKP hierarchy.

*Remark 1.* Consider a set  $S$ , which consists of distinct non-negative integers and includes zero. By  $\text{DP}_S$  we denote the subset of all strict partitions whose parts belong to the set  $S$ . By the limiting procedure:  $e^{\xi_k} \rightarrow 0$  iff  $k$  does not belong to the set  $S$ , we can restrict the sum in (1) to the set  $\text{DP}_S$ . If  $S$  is a finite set, then (1) is a polynomial in  $\mathbf{t}_o$  which describes a *rational* solution of the BKP hierarchy.

The typical choice of the BKP higher times is the following:

$$mt_m = \sum_k^N (x_k^m - (-x_k)^m), \quad mt_m^* = \sum_k^{N^*} (y_k^m - (-y_k)^m). \quad (2)$$

---

†Oceanology Institute, Nahimovskii Prospekt 36, Moscow, Russia, email: orlovs@wave.sio.rssi.ru

In this case the sum in (1) ranges over all partitions whose length do not exceed  $k = \min(N, N^*)$ .

We note that a special case of this series (1), where times were chosen as in (2), and  $e^{\xi_m}$  was chosen as a step function, was considered in [16] in a combinatorial context, not related to integrable systems.

In the present paper, we will specialize the variables  $\mathbf{t}_o^*$  as  $\mathbf{t}_\infty = (1, 0, 0, \dots)$ , and study the  $\tau$ -function (1) as a function of the variables  $\xi_m$ . We find that series (1) is a multi-soliton  $\tau$ -function of a different integrable hierarchy, which we call the dual BKP hierarchy. The variables  $\xi_m$  of (1) turn out to be linear combinations of the time variables  $\tilde{\mathbf{t}}_o = (\tilde{t}_1, \tilde{t}_3, \dots)$  of the dual BKP hierarchy. We observe that the variables  $\xi_m$  (proportional to the times of the dual BKP hierarchy) are integrals of motion of the original BKP hierarchy and, simultaneously, the times  $\mathbf{t}_o$  of the original BKP hierarchy are integrals of motion of the dual BKP hierarchy. That is why we call these hierarchies dual to one another.

The situation we will describe is closely related to corresponding results for the hypergeometric  $\tau$ -functions of the KP hierarchy. These  $\tau$ -functions are described as hypergeometric because they generalize some known hypergeometric functions of many variables, see [18, 19]. We note that the KP hypergeometric  $\tau$ -functions yields a perturbative asymptotic expansion for a set of known matrix integrals [10, 27]. They were also used to construct new solvable matrix integrals [28, 29]. Other examples of hypergeometric  $\tau$ -functions arise in supersymmetric gauge theories [20], [21], in the problem of counting of Hurwitz numbers [22], in counting Gromov-Witten invariants of  $P^1$  [23] and in the computation of intersection numbers on Hilbert schemes [24]. In references [30, 31],  $\tau$ -functions, which were considered in the context of  $c = 1$  strings, are also of hypergeometric type. The series for two dimensional QCD, considered in [25, 26], may be related to the KP hypergeometric  $\tau$ -functions also. We anticipate that applications of similar series in  $Q$ -functions are found also.

The series (1) can be studied in the context of random strict partitions. Series (1) generalizes the sums over random partitions which are considered in [16].

With regard to notation used in this paper, we will use infinite sequences of higher times

$$\mathbf{t} = (t_1, t_2, t_3, \dots), \quad \mathbf{t}^* = (t_1^*, t_2^*, t_3^*, \dots), \quad (3)$$

$$\mathbf{t}_o = (t_1, t_3, t_5, \dots), \quad \mathbf{t}_o^* = (t_1^*, t_3^*, t_5^*, \dots), \quad (4)$$

and, when they appear as higher times in dual equations will be marked with a tilde. Special cases of these,  $\mathbf{t}_\infty$  and  $\mathbf{t}_o(q)$ , will be defined in (80) and (81) below.

## 2 KP and BKP $\tau$ -functions

In this section we will summarise the essential facts about  $\tau$ -functions for the KP and BKP hierarchies as given in [1]. The definitions of terms related to symmetric functions may be found in [6].

### 2.1 Schur functions as KP $\tau$ -functions

Let  $A$  be the complex Clifford algebra generated by the *charged free fermions*  $\psi_i, \psi_i^*$ , where  $i \in \mathbb{Z}$  with anticommutation relations

$$[\psi_i, \psi_j]_+ = [\psi_i^*, \psi_j^*]_+ = 0, \quad [\psi_i, \psi_j^*]_+ = \delta_{i,j}. \quad (5)$$

Consider also the generators

$$\psi(p) = \sum_{k \in \mathbb{Z}} \psi_k p^k, \quad \psi^*(q) = \sum_{k \in \mathbb{Z}} \psi_k^* q^{-k-1}. \quad (6)$$

The vacuum expectation value is a linear functional  $\langle \cdot \rangle: A \rightarrow \mathbb{C}$ . For linear and quadratic elements in  $A$  it is defined by  $\langle \psi_i \rangle = \langle \psi_i^* \rangle = \langle \psi_i \psi_j \rangle = \langle \psi_i^* \psi_j^* \rangle = 0$  and

$$\langle \psi_i \psi_j^* \rangle = \begin{cases} \delta_{i,j} & i < 0 \\ 0 & i \geq 0 \end{cases}, \quad \langle \psi_i^* \psi_j \rangle = \begin{cases} \delta_{i,j} & i \geq 0 \\ 0 & i < 0 \end{cases}. \quad (7)$$

For an arbitrary product of linear terms in  $A$ , Wick's Theorem gives

$$\langle 0|w_1 \cdots w_{2n+1}|0\rangle = 0, \quad \langle 0|w_1 \cdots w_{2n}|0\rangle = \sum_{\sigma} \text{sgn}(\sigma) \langle 0|w_{\sigma(1)}w_{\sigma(2)}|0\rangle \cdots \langle 0|w_{\sigma(2n-1)}w_{\sigma(2n)}|0\rangle, \quad (8)$$

where  $w_k$  are linear terms in  $A$ , and  $\sigma$  runs over permutations such that  $\sigma(1) < \sigma(2), \dots, \sigma(2n-1) < \sigma(2n)$ , and  $\sigma(1) < \sigma(3) < \dots < \sigma(2n-1)$ .

The connection between the anticommutation relations and the vacuum expectation value is that  $[w_1, w_2]_+ = \langle w_1 w_2 \rangle + \langle w_2 w_1 \rangle$ .

For free fermion generators with  $|p| \neq |q|$ ,

$$\langle \psi(p)\psi^*(q) \rangle = \frac{1}{p-q}, \quad (9)$$

and for higher degree products, Wick's Theorem gives

$$\begin{aligned} \langle \psi(p_1)\psi^*(q_1) \cdots \psi(p_n)\psi^*(q_n) \rangle &= \det(\langle \psi(p_i)\psi^*(q_j) \rangle) \\ &= \prod_i \frac{1}{p_i - q_i} \prod_{i < j} \frac{(p_i - p_j)(q_i - q_j)}{(p_i - q_j)(q_i - p_j)}. \end{aligned} \quad (10)$$

Time evolution enters  $A$  via the hamiltonian

$$H(\mathbf{t}) = \sum_{n=1}^{\infty} H_n t_n, \quad (11)$$

where

$$H_n = \sum_{k \in \mathbb{Z}} \psi_k \psi_{k+n}^*. \quad (12)$$

For any  $a \in A$ , we define

$$a(\mathbf{t}) = e^{H(\mathbf{t})} a e^{-H(\mathbf{t})} = \exp(\text{ad } H(\mathbf{t})) a, \quad (13)$$

and it may be shown that

$$\psi(p)(\mathbf{t}) = \exp(\xi(p, \mathbf{t})) \psi(p), \quad \psi^*(q)(\mathbf{t}) = \exp(-\xi(q, \mathbf{t})) \psi^*(q), \quad (14)$$

where  $\xi(p, \mathbf{t}) = \sum_{k=1}^{\infty} p^k t_k$ .

Consider  $g \in A$ , which solves the following bilinear equation

$$\left[ g \otimes g, \sum_{n=-\infty}^{\infty} \psi_n \otimes \psi_n^* \right] = 0, \quad (15)$$

where the notation  $[, ]$  stands for the commutator, and  $\otimes$  is the tensor product. Then, one has a  $\tau$ -function

$$\tau(\mathbf{t}) = \langle g(\mathbf{t}) \rangle. \quad (16)$$

The simplest type of  $\tau$ -functions correspond to multi-soliton solution of the KP hierarchy. Taking  $g = \exp(\sum_{i=1}^n a_i \psi(p_i) \psi^*(q_i))$  gives the  $n$ -soliton  $\tau$ -function

$$\tau(\mathbf{t}) = \det \left( \delta_{i,j} + \frac{a_i}{p_i - q_j} e^{\xi(p_i, \mathbf{t}) - \xi(q_j, \mathbf{t})} \right), \quad (17)$$

where

$$\xi(p, \mathbf{t}) = \sum_{m=1}^{\infty} p^m t_m \quad (18)$$

Later, we will also need the soliton solution of the two-dimensional Toda lattice equation (TL) [32], which is described by almost the same formula

$$\tau(n, \mathbf{t}, \mathbf{t}^*) = A(\mathbf{t}, \mathbf{t}^*) \det \left( \delta_{i,j} + \frac{a_i}{p_i - q_j} e^{\xi(p_i, n, \mathbf{t}, \mathbf{t}^*) - \xi(q_j, n, \mathbf{t}, \mathbf{t}^*)} \right), \quad (19)$$

where

$$\xi(p, n, \mathbf{t}, \mathbf{t}^*) = \sum_{m=1}^{\infty} (p^m t_m - p^{-m} t_m^*) + n \log p \quad (20)$$

and

$$A(\mathbf{t}, \mathbf{t}^*) = e^{\sum_{m=1}^{\infty} m t_m t_m^*} \quad (21)$$

which is usually omitted from the definition of the TL  $\tau$ -function [32] since the transformation to nonlinear variables removes it from the TL solution. We will also neglect this term for the same reason. It is well-known [32], that any TL  $\tau$ -function is a  $\tau$ -function of the pair of KP hierarchies with higher times respectively  $\mathbf{t}$  and  $\mathbf{t}^*$ . There exists a reduction to the one-dimensional TL, which yields also a reduction to the nonlinear Schrödinger equation. This reduction is described by the demand that the  $\tau$ -function of the two-dimensional TL (up to the irrelevant factor (21)) depends only on  $\mathbf{t} + \mathbf{t}^*$ . It is provided by the condition  $q_i = p_i^{-1}$  in (19) and we will use it in what follows. We shall also use the reduction to KdV, namely the choice  $q_i = -p_i$  in (17). The KdV  $\tau$ -function depends only on the odd index KP higher times, that is, on the sequence  $\mathbf{t}_o$ .

Polynomial  $\tau$ -functions are obtained by considering expansions in the parameters  $p_i$  and  $q_j$ . First, elementary Schur polynomials  $s_i(\mathbf{t})$  are defined by

$$\exp(\xi(p, \mathbf{t})) = \sum_{k \geq 0} s_i(\mathbf{t}) p^k. \quad (22)$$

Since

$$1 = \exp(\xi(p, \mathbf{t})) \exp(-\xi(p, \mathbf{t})) = \sum_{i \geq 0} \sum_{j=0}^i s_{i-j}(\mathbf{t}) s_j(-\mathbf{t}) p^i, \quad (23)$$

we have the orthogonality condition

$$\sum_{j=0}^i s_{i-j}(\mathbf{t}) s_j(-\mathbf{t}) = \delta_{i,0}. \quad (24)$$

For all non-negative integers we can define

$$s_{(a|b)}(\mathbf{t}) = (-1)^b \sum_{k=0}^b s_{a+1+k}(\mathbf{t}) s_{b-k}(-\mathbf{t}) = (-1)^{b+1} \sum_{k=0}^a s_k(\mathbf{t}) s_{a+b+1-k}(-\mathbf{t}). \quad (25)$$

This is the Schur function for the partition  $(a+1, b^j)$ , which is written using Frobenius notation as  $(a|b)$ . This result is easily proved using the Jacobi-Trudi identity. For any partition function written in Frobenius notation,

$$s_{(a_1 a_2 \dots a_n | b_1 b_2 \dots b_n)}(\mathbf{t}) = \det(s_{(a_i | b_j)}). \quad (26)$$

Using this notation, (14) gives

$$\psi_i(\mathbf{t}) = \sum_{k \geq 0} s_k(\mathbf{t}) \psi_{i-k}, \quad \psi_i^*(\mathbf{t}) = \sum_{k \geq 0} s_k(-\mathbf{t}) \psi_{i+k}^*. \quad (27)$$

Consequently,

$$\langle \psi_i(\mathbf{t}) \psi_j^*(\mathbf{t}) \rangle = \sum_{k, \ell \geq 0} s_k(\mathbf{t}) s_\ell(-\mathbf{t}) \langle \psi_{i-k} \psi_{j+\ell}^* \rangle = \sum_{k=i+1}^{i-j} s_k(\mathbf{t}) s_{i-j-k}(-\mathbf{t}). \quad (28)$$

Hence we see that

$$s_{(a|b)}(\mathbf{t}) = (-1)^{b+1} \langle \psi_a(\mathbf{t}) \psi_{-b-1}^*(\mathbf{t}) \rangle, \quad (29)$$

that is that  $s_{(a|b)}$  is the KP  $\tau$ -function for  $g = (-1)^{b+1} \psi_a \psi_{-b-1}^*$ . More generally, this shows that an arbitrary Schur function  $s_{(a_1 \dots a_n | b_1 \dots b_n)}$ , is a KP  $\tau$ -function for

$$g = (-1)^{b_1 + \dots + b_n + n} \psi_{a_1} \psi_{-b_1-1}^* \dots \psi_{a_n} \psi_{-b_n-1}^*.$$

## 2.2 $Q$ -functions as BKP $\tau$ -functions

The subalgebra of  $A$  invariant under the symmetry

$$\psi_i \leftrightarrow (-1)^i \psi_{-i}^* \quad (30)$$

is used in a similar way to determine BKP  $\tau$ -functions. There are two bases of *neutral free fermions*

$$\phi_i = \frac{1}{\sqrt{2}}(\psi_i + (-1)^i \psi_{-i}^*), \quad \hat{\phi}_i = \frac{i}{\sqrt{2}}(\psi_i - (-1)^i \psi_{-i}^*), \quad (31)$$

where  $i \in \mathbb{Z}$ , each of which generates this subalgebra.

Using the results for charged free fermions, the anticommutation relations are

$$[\phi_i, \phi_j]_+ = [\hat{\phi}_i, \hat{\phi}_j]_+ = (-1)^i \delta_{i,-j}, \quad [\phi_i, \hat{\phi}_j]_+ = 0, \quad (32)$$

and, in particular,  $\phi_0^2 = \hat{\phi}_0^2 = \frac{1}{2}$ . Similarly, the vacuum expectation values of quadratic elements are given by

$$\langle \phi_i \phi_j \rangle = \langle \hat{\phi}_i \hat{\phi}_j \rangle = \begin{cases} (-1)^i \delta_{i,-j} & i < 0 \\ \frac{1}{2} \delta_{j,0} & i = 0, \\ 0 & i > 0 \end{cases}, \quad (33)$$

and Wick's Theorem is used for arbitrary degree products.

The neutral free fermion generator is defined by  $\phi(p) = \sum_{n \in \mathbb{Z}} p^n \phi_n$ . We have (for  $|p| \neq |p'|$ )

$$\langle \phi(p) \phi(p') \rangle = \frac{1}{2} \frac{p - p'}{p + p'}, \quad (34)$$

and  $\langle \phi(p') \phi(p) \rangle = -\langle \phi(p) \phi(p') \rangle$ . By Wick's Theorem we get

$$\langle \phi(p_1) \phi(p_2) \cdots \phi(p_N) \rangle = \begin{cases} \text{Pf}(\langle \phi(p_i) \phi(p_j) \rangle) & N \text{ even} \\ 0 & \text{otherwise} \end{cases} = \begin{cases} 2^{-N/2} \prod_{i < j} \frac{p_i - p_j}{p_i + p_j} & N \text{ even} \\ 0 & \text{otherwise} \end{cases}. \quad (35)$$

The connection between the charged and neutral free fermions can be expressed in terms of the generators as

$$-q\psi(p)\psi^*(-q) + p\psi(q)\psi^*(-p) = \phi(p)\phi(q) + \hat{\phi}(p)\hat{\phi}(q). \quad (36)$$

In the BKP reduction, even times are set equal to zero and we define  $\mathbf{t}_o = (t_1, 0, t_3, 0, t_5, \dots)$ , and the hamiltonian

$$H^B(\mathbf{t}_o) = \sum_{i \geq 1, \text{ odd}} H_n^B t_n, \quad (37)$$

where

$$H_n^B = \frac{1}{2} \sum_{i \in \mathbb{Z}} (-1)^{i+1} \phi_i \phi_{-i-n}. \quad (38)$$

For the fermion generating function one has

$$\phi(p)(\mathbf{t}_o) = e^{H^B(\mathbf{t}_o)} \phi(p) e^{-H^B(\mathbf{t}_o)} = e^{\hat{H}^B(\mathbf{t}_o)} \phi(p) e^{-\hat{H}^B(\mathbf{t}_o)} = e^{\xi(p, \mathbf{t}_o)} \phi(p). \quad (39)$$

Note also that

$$H(\mathbf{t}_o) = H^B(\mathbf{t}_o) + \hat{H}^B(\mathbf{t}_o), \quad [H^B(\mathbf{t}_o), \hat{H}^B(\mathbf{t}_o)] = 0. \quad (40)$$

Similar to the KP case, BKP  $\tau$ -functions are defined by

$$\tau_B(\mathbf{t}_o) = \langle h(\mathbf{t}_o) \rangle, \quad (41)$$

where  $h$  is the Clifford algebra of the neutral free fermions  $\phi_i$ . The  $n$ -soliton  $\tau$ -function is obtained by the choice  $g = \exp(\sum_{i=1}^n a_i \phi(p_i) \phi(q_i))$ .

The Schur  $q$  polynomials are defined by

$$\exp(2\xi(p, \mathbf{t}_o)) = \sum_{k \geq 0} q_k(\mathbf{t}_o) p^k. \quad (42)$$

Thus

$$\phi_i(\mathbf{t}_o) = \sum_{k \geq 0} q_k(\frac{1}{2}\mathbf{t}_o) \phi_{i-k}. \quad (43)$$

We have

$$\langle \phi_i(\mathbf{t}_o) \phi_j(\mathbf{t}_o) \rangle = \frac{1}{2} q_i(\frac{1}{2}\mathbf{t}_o) q_j(\frac{1}{2}\mathbf{t}_o) + \sum_{k=1}^j (-1)^k q_{k+i}(\frac{1}{2}\mathbf{t}_o) q_{j-k}(\frac{1}{2}\mathbf{t}_o). \quad (44)$$

Since

$$1 = \exp(2\xi(p, \mathbf{t}_o)) \exp(-2\xi(p, \mathbf{t}_o)) = \sum_{i,j} q_i(\mathbf{t}_o) q_{j-i}(-\mathbf{t}_o) = \sum_{i,j} (-1)^{i-j} q_i(\mathbf{t}_o) q_{j-i}(\mathbf{t}_o) p^j, \quad (45)$$

for all  $n > 0$  we have

$$\sum_{i=0}^n (-1)^i q_i(\mathbf{t}_o) q_{n-i}(\mathbf{t}_o) = 0. \quad (46)$$

This is trivial if  $n$  is odd and if  $n = 2m$  is even then it gives

$$q_m(\mathbf{t}_o)^2 + 2 \sum_{k=1}^m (-1)^k q_{m+k}(\mathbf{t}_o) q_{m-k}(\mathbf{t}_o) = 0. \quad (47)$$

We can also define

$$q_{a,b}(\mathbf{t}_o) = q_a(\mathbf{t}_o) q_b(\mathbf{t}_o) + 2 \sum_{k=1}^b (-1)^k q_{a+k}(\mathbf{t}_o) q_{b-k}(\mathbf{t}_o). \quad (48)$$

It follows from the orthogonality condition (46) that

$$q_{a,b}(\mathbf{t}_o) = -q_{b,a}(\mathbf{t}_o), \quad (49)$$

and in particular,  $q_{a,a}(\mathbf{t}_o) = 0$ . Comparing (44) and (48), it is clear that

$$q_{a,b}(\frac{1}{2}\mathbf{t}_o) = 2 \langle \phi_a(\mathbf{t}_o) \phi_b(\mathbf{t}_o) \rangle. \quad (50)$$

Now consider  $\lambda = (\lambda_1, \lambda_2, \dots, \lambda_{2n})$  where  $\lambda_1 > \lambda_2 > \dots > \lambda_{2n-1} > \lambda_{2n} \geq 0$ . Note that this is a partition with an extra trivial part 0 included if necessary to ensure that the number of parts is even. The set of such strict, or distinct part, partitions is denoted DP. For  $\lambda \in \text{DP}$  we define

$$Q_\lambda(\frac{1}{2}\mathbf{t}_o) = \text{Pf}(q_{\lambda_i, \lambda_j}(\frac{1}{2}\mathbf{t}_o)). \quad (51)$$

This is the Schur  $Q$ -function. By Wick's theorem,

$$Q_\lambda(\frac{1}{2}\mathbf{t}_o) = \text{Pf}(2 \langle \phi_{\lambda_i}(\mathbf{t}_o) \phi_{\lambda_j}(\mathbf{t}_o) \rangle) = 2^n \langle \phi_{\lambda_1}(\mathbf{t}_o) \phi_{\lambda_2}(\mathbf{t}_o) \cdots \phi_{\lambda_{2n}}(\mathbf{t}_o) \rangle.$$

### 2.3 Hypergeometric $\tau$ -functions

These  $\tau$ -functions were introduced by one of the authors in the KP case [8] and the BKP case [9].

In the KP case, let  $r$  be a function of one variable and for any partition  $\lambda$ , let  $r_\lambda(x) = \prod_{(i,j) \in \lambda} r(x - i + j)$ , the product being over all vertices in the Young diagram. Then

$$\tau(n, \mathbf{t}, \mathbf{t}^*) = \sum_{\lambda} r_\lambda(n) s_\lambda(\mathbf{t}) s_\lambda(\mathbf{t}^*) \quad (52)$$

where  $\mathbf{t} = (t_1, t_2, t_3, \dots)$ ,  $\mathbf{t}^* = (t_1^*, t_2^*, t_3^*, \dots)$ , is the KP hypergeometric  $\tau$ -function.

In the BKP case,  $r_\lambda$  has a different definition: if  $\lambda = (\lambda_1, \dots, \lambda_k)$  then  $r_\lambda = \prod_{i=1}^k r(1)r(2) \cdots r(\lambda_i)$ . If we introduce new variables  $r(k) = e^{\xi_k - \xi_{k-1}}$ ,  $\xi_{-1} = 0$  then  $r_\lambda = \prod_{i=1}^{\ell(\lambda)} e^{\xi_{\lambda_i}}$

With these definitions,

$$\tau(\mathbf{t}_o, \xi, \mathbf{t}_o^*) = \sum_{\lambda \in \text{DP}} 2^{-\ell(\lambda)} r_\lambda Q_\lambda(\frac{1}{2}\mathbf{t}_o) Q_\lambda(\frac{1}{2}\mathbf{t}_o^*) = \sum_{\lambda \in \text{DP}} 2^{-\ell(\lambda)} \prod_{i=1}^{\ell(\lambda)} e^{\xi_{\lambda_i}} Q_\lambda(\frac{1}{2}\mathbf{t}_o) Q_\lambda(\frac{1}{2}\mathbf{t}_o^*) \quad (53)$$

is the BKP hypergeometric  $\tau$ -function. By Remark 1 one can restrict sum (53) to the sum which ranges over  $\text{DP}_S$ .

It can be show that this is a  $\tau$ -function since

$$\tau(\mathbf{t}_o, \xi, \mathbf{t}_o^*) = \langle 0 | e^{\sum_{i \geq 1, \text{ odd}} H_n^B t_n} e^{\sum_{n=-\infty}^{\infty} (-)^n \xi_n \cdot \phi_n \phi_{-n}} e^{\sum_{i \geq 1, \text{ odd}} H_{-n}^B t_n^*} | 0 \rangle \quad (54)$$

### 3 Main results

#### 3.1 KP infinite soliton solution

Let

$$g^{\text{sol}} = \exp \left( \sum_{i,j \geq 0} a_{i,j} \psi(p_i) \psi^*(q_j) \right) \quad (55)$$

Then

$$\begin{aligned} \tau^{\text{sol}} &:= \langle g^{\text{sol}}(\mathbf{t}) \rangle \quad (56) \\ &= 1 + \sum_{i,j} a_{i,j} \langle \psi(p_i) \psi^*(q_j)(\mathbf{t}) \rangle + \sum_{i,j,k,l} (a_{i,j} a_{k,l} - a_{i,l} a_{j,k}) \langle \psi(p_i) \psi^*(q_j) \psi(p_k) \psi^*(q_l)(\mathbf{t}) \rangle + \cdots \\ &= 1 + \sum_{i,j} \binom{i}{j} \frac{1}{p_i - q_j} e^{\xi(p_i, \mathbf{t}) - \xi(q_j, \mathbf{t})} \\ &\quad + \sum_{i,j,k,l} \binom{i,j}{k,l} \frac{1}{(p_i - q_j)(p_k - q_l)} \frac{(p_i - p_k)(q_j - q_l)}{(p_i - q_l)(q_j - p_k)} e^{\xi(p_i, \mathbf{t}) - \xi(q_j, \mathbf{t}) + \xi(p_k, \mathbf{t}) - \xi(q_l, \mathbf{t})} + \dots, \end{aligned}$$

where

$$\binom{i,j}{k,l}, \quad (57)$$

denotes the  $2 \times 2$  minor of the infinite matrix  $(a_{i,j})$  containing the  $i$ th and  $j$ th rows and the  $k$ th and  $l$ th columns.

If  $a_{i,j} = s_{(i|j)}(\mathbf{t}^*)$  then the coefficients can be written as

$$s_\lambda(\mathbf{t}^*) \quad (58)$$

for all partitions  $\lambda$ .

#### 3.2 KdV soliton solution

The KdV reduction of the KP soliton solution (17),

$$g_{\text{KdV}}^{\text{sol}} = \exp \left( \sum_{i \geq 0} a_i p_i \psi(p_i) \psi^*(-p_i) \right), \quad (59)$$

gives rise to the following soliton  $\tau$ -function, which depends only on the higher KP times with odd numbers  $\mathbf{t}_o = (t_1, t_3, t_5, \dots)$ ,

$$\begin{aligned} \tau_{\text{KdV}}^{\text{sol}} &:= \langle g_{\text{KdV}}^{\text{sol}}(\mathbf{t}_o) \rangle = \det \left( \delta_{i,j} + \frac{a_i p_i}{p_i + p_j} e^{\xi(p_i, \mathbf{t}_o) - \xi(-p_i, \mathbf{t}_o)} \right) \\ &= 1 + \sum_i \frac{1}{2} e^{\eta_i} + \sum_{i>j} \frac{1}{2^2} \frac{(p_i - p_j)^2}{(p_i + p_j)^2} e^{\eta_i + \eta_j} \\ &\quad + \sum_{i>j>k} \frac{1}{2^3} \frac{(p_i - p_j)^2 (p_i - p_k)^2 (p_j - p_k)^2}{(p_i + p_j)^2 (p_i + p_k)^2 (p_j + p_k)^2} e^{\eta_i + \eta_j + \eta_k} + \dots, \end{aligned} \quad (60)$$

where

$$\eta_i = 2 \sum_{m=1}^{\infty} t_{2m-1} p_i^{2m-1} + \log a_i, \quad i = 0, 1, 2, \dots \quad (61)$$

*Remark 2.* We note that the fractional linear transformation of the (complex) plane of spectral parameters  $p_i \in \mathbb{C}$

$$p_i \rightarrow \frac{ap_i + b}{cp_i + d}, \quad \frac{ad - bc}{ad + bc} = \pm 1, \quad i = 1, 2, \dots \quad (62)$$

leaves invariant the factors

$$\frac{(p_i - p_j)^2}{(p_i + p_j)^2}, \quad i, j = 1, 2, \dots \quad (63)$$

It is easy to see that there are two distinct types of invariance;  $a = d = 0, b, c \neq 0$  and  $a, d \neq 0, b = c = 0$ .

### 3.3 NLS and one-dimensional Toda lattice soliton $\tau$ -function

Let us consider the reduction of the TL soliton  $\tau$ -function (19) to the one-dimensional Toda lattice (1DTL) reduction, which is  $q_i = p_i^{-1}$ , see [32]. If, in addition,  $|p_i| = 1$ , then, it is also a reduction to the nonlinear Schrödinger equation (NLS). For the multi-soliton tau function we have

$$g_{\text{1DTL}}^{\text{sol}} = \exp \left( \sum_{i \geq 0} \frac{a_i}{2} (p_i - p_i^{-1}) \psi(p_i) \psi^*(p_i^{-1}) \right) \quad (64)$$

$$\begin{aligned} \tau_{\text{1DTL}}^{\text{sol}}(n, \mathbf{t}, \mathbf{t}^*) &= \tau_{\text{1DTL}}^{\text{sol}}(n, \mathbf{t} + \mathbf{t}^*) := \\ &= \langle g_{\text{1DTL}}^{\text{sol}}(n, \mathbf{t}, \mathbf{t}^*) \rangle = \det \left( \delta_{i,j} + \frac{a_i (p_i - p_i^{-1})}{2(p_i - p_j^{-1})} e^{\xi(p_i, n, \mathbf{t}, \mathbf{t}^*) - \xi(p_j^{-1}, n, \mathbf{t}, \mathbf{t}^*)} \right) \\ &= 1 + \sum_i \frac{1}{2} e^{\eta_i} + \sum_{i>j} \frac{1}{2^2} \frac{(p_i - p_j)^2}{(p_i p_j - 1)^2} e^{\eta_i + \eta_j} \\ &\quad + \sum_{i>j>k} \frac{1}{2^3} \frac{(p_i - p_j)^2 (p_i - p_k)^2 (p_j - p_k)^2}{(p_i p_j - 1)^2 (p_i p_k - 1)^2 (p_j p_k - 1)^2} e^{\eta_i + \eta_j + \eta_k} + \dots, \end{aligned} \quad (65)$$

where  $\mathbf{t} = (t_1, t_2, t_3, \dots)$ ,  $\mathbf{t}^* = (t_1^*, t_2^*, t_3^*, \dots)$ , and

$$\eta_i = \sum_{m=1}^{\infty} (p_i^m - p_i^{-m}) (t_m + t_m^*) + 2n \log p_i + \log a_i, \quad i = 0, 1, 2, \dots \quad (66)$$

For the nonlinear Schrödinger equation the  $n$ -dependence of the  $\tau$ -function is irrelevant.

*Remark 3.* Here, the fractional linear transformations

$$p_i \rightarrow \pm \frac{ap_i + b}{bp_i + a}, \quad i = 0, 1, 2, \dots \quad (67)$$

where  $a$  and  $b$  are not both zero, leave invariant the factors

$$\frac{(p_i - p_j)^2}{(p_i p_j - 1)^2}, \quad i, j = 0, 1, 2, \dots \quad (68)$$

### 3.4 BKP infinite soliton solution

Now writing  $q_i = -p_i$  and choosing skew-symmetric matrix entries  $a_{ji} = -a_{ij}$  in (55) gives

$$g^{\text{sol}} = \exp \left( \sum_{0 \leq i < j} a_{i,j} (-p_j \psi(p_i) \psi^*(-p_j) + p_i \psi(p_j) \psi^*(-p_i)) \right). \quad (69)$$

By (36) this may be rewritten as

$$g^{\text{sol}} = \exp \left( \sum_{0 \leq i < j} a_{i,j} (\phi(p_i) \phi(p_j) + \hat{\phi}(p_i) \hat{\phi}(p_j)) \right). \quad (70)$$

Since  $[\phi_i, \hat{\phi}_j]_+ = 0$ ,  $[\phi_i \phi_k, \hat{\phi}_j \hat{\phi}_l] = 0$  and so we can factorize as  $g = h \hat{h}$  where

$$h = \exp \left( \sum_{i < j} a_{i,j} \phi(p_i) \phi(p_j) \right), \quad \hat{h} = \exp \left( \sum_{i < j} a_{i,j} \hat{\phi}(p_i) \hat{\phi}(p_j) \right). \quad (71)$$

Then, we have

$$\begin{aligned} \tau_{\mathbb{B}}^{\text{sol}}(\mathbf{t}_o) &:= \langle h(\mathbf{t}_o) \rangle = \langle \hat{h}(\mathbf{t}_o) \rangle \\ &= 1 + \sum_{0 \leq i < j} a_{i,j} \langle \phi(p_i) \phi(p_j)(\mathbf{t}_o) \rangle \\ &\quad + \sum_{0 \leq i < j < k < l} (a_{i,j} a_{k,l} - a_{i,k} a_{j,l} + a_{i,l} a_{j,k}) \langle \phi(p_i) \phi(p_j) \phi(p_k) \phi(p_l)(\mathbf{t}_o) \rangle + \dots \\ &= 1 + \sum_{0 \leq i < j} (i, j) \frac{1}{2} \frac{p_i - p_j}{p_i + p_j} e^{\xi(p_i, \mathbf{t}_o) + \xi(p_j, \mathbf{t}_o)} \\ &\quad + \sum_{0 \leq i < j < k < l} (i, j, k, l) \frac{1}{2^2} \frac{(p_i - p_j)(p_k - p_l)}{(p_i + p_j)(p_k + p_l)} e^{\xi(p_i, \mathbf{t}_o) + \xi(p_j, \mathbf{t}_o) + \xi(p_k, \mathbf{t}_o) + \xi(p_l, \mathbf{t}_o)} + \dots, \end{aligned} \quad (72)$$

where

$$(i, j, k, l), \quad (73)$$

denotes the pfaffian minor of the infinite skew-symmetric matrix  $(a_{ij})$  containing the  $i$ th,  $j$ th,  $k$ th and  $l$ th lines. Using (40) gives

$$\tau^{\text{sol}}(\mathbf{t}_o) = \tau_{\mathbb{B}}^{\text{sol}}(\mathbf{t}_o)^2. \quad (74)$$

If  $a_{i,j} = q_{i,j}(\frac{1}{2}\mathbf{t}_o^*)$  then the coefficients can be written as

$$Q_{\lambda}(\frac{1}{2}\mathbf{t}_o^*) \quad (75)$$

for all partitions  $\lambda$  into distinct parts.

*Remark 4.* The factors

$$(i, j) \frac{p_i - p_j}{p_i + p_j}, \quad (i, j, k, l) \frac{(p_i - p_j)(p_k - p_l)}{(p_i + p_j)(p_k + p_l)}, \dots$$

in (72), are invariant under the transformation

$$p_i \rightarrow \frac{ap_i + b}{cp_i + d}, \quad i = 0, 1, 2, \dots, \quad (76)$$

$$a_{i,j} \rightarrow \gamma a_{i,j}, \quad i, j = 0, 1, 2, \dots, \quad (77)$$

where  $a, b, c, d$  are any complex numbers such that

$$\frac{ad + bc}{ad - bc} = \gamma, \quad (78)$$

is not zero or infinity.

*Remark 5.* Although the free fermion generator is not defined if its parameter is 0, i.e.  $\phi(0)$  does not make sense, the limit

$$\lim_{p' \rightarrow 0} \langle \phi(p)\phi(p') \rangle = \frac{1}{2} \quad (79)$$

as given by (35), is well defined.

### 3.5 Useful Lemma

Let us introduce the following notation:

$$\mathbf{t}_\infty = (1, 0, 0, 0, \dots), \quad (80)$$

and

$$\mathbf{t}_o(q) = (t_1(q), t_3(q), t_5(q), \dots), \quad t_{2m-1}(q) = \frac{2}{(2m-1)(1-q^{2m-1})}, \quad t_{2m} = 0, \quad m = 1, 2, \dots \quad (81)$$

*Remark 6.* Let us notice that  $\mathbf{t}_\infty$  can be viewed as given by (2), where we take  $x_1 = x_2 = \dots = x_N = N^{-1}$  and  $N \rightarrow \infty$ . Similarly,  $\mathbf{t}_o(q)$  is given by (2), where  $x_k = q^{k-1}$ ,  $k = 1, 2, \dots$ . As for  $\mathbf{t}_\infty$ , if  $f$  satisfies  $f(ct_1, c^3t_3, c^5t_5, \dots) = c^d f(t_1, t_3, t_5, \dots)$  for some  $d \in \mathbb{Z}$ , we have  $\hbar^d f(\mathbf{t}_o(q)) \rightarrow f(\mathbf{t}_\infty)$  as  $\hbar := \log q \rightarrow 0$ . In that sense (80) may be considered as a limit of (81) as  $q \rightarrow 1$ .

We have

**Lemma 1.** *Let  $\lambda = (\lambda_1, \dots, \lambda_k)$  be a strict partition. Then*

$$Q_\lambda(\frac{1}{2}\mathbf{t}_\infty) = \prod_{i=1}^k \frac{1}{\lambda_i!} \prod_{i < j}^k \frac{\lambda_i - \lambda_j}{\lambda_i + \lambda_j}, \quad (82)$$

and

$$Q_\lambda(\frac{1}{2}\mathbf{t}_o(q)) = \prod_{i < j}^k \frac{q^{\lambda_i} - q^{\lambda_j}}{q^{\lambda_j + \lambda_i} - 1} \prod_{i=1}^k \frac{(-q; q)_{\lambda_i}}{(q; q)_{\lambda_i}}, \quad (83)$$

where

$$(p; q)_m := (1-p)(1-pq) \cdots (1-pq^{m-1}) \quad (84)$$

### 3.6 Hypergeometric functions related to the projective Schur functions

We consider hypergeometric  $\tau$ -functions (1), where we specialize the variable  $\mathbf{t}_o^*$  respectively by (80) and (81):

$$\tau(\mathbf{t}_o, \xi, \mathbf{t}_\infty) = \sum_{\lambda \in \text{DP}_S} \frac{Q_\lambda(\frac{1}{2}\mathbf{t}_o)}{2^{\ell(\lambda)} H_\lambda^*} \prod_{i=1}^{\ell(\lambda)} e^{\xi n_i}, \quad (85)$$

$$\tau(\mathbf{t}_o, \xi, \mathbf{t}_o(q)) = \sum_{\lambda \in \text{DP}_S} \frac{Q_\lambda(\frac{1}{2}\mathbf{t}_o)}{2^{\ell(\lambda)} H_\lambda^*(q)} \prod_{i=1}^{\ell(\lambda)} e^{\xi n_i}, \quad (86)$$

where

$$H_\lambda^* = Q_\lambda(\frac{1}{2}\mathbf{t}_\infty)^{-1}, \quad H_\lambda^*(q) = Q_\lambda(\frac{1}{2}\mathbf{t}_o(q))^{-1} \quad (87)$$

are respectively so-called product-of-shifted-hook-length [6], which generalize the notion of the factorial for strict partitions and its  $q$ -analog (shifted hook polynomial). We took into account Remark 1, to restrict sums over all strict partitions to the subset  $\text{DP}_S$ .

In the case that  $\text{DP}_S$  is the set of all strict partitions, namely,  $\text{DP}$ , the series (85) and (86) may be considered as multi-variable generalization of hypergeometric function (respectively, basic hypergeometric function), which we obtain when  $\ell(\lambda) = 1$  and  $\mathbf{t}_o$  is of form (2) where  $N_1 = 1$ .

The notation  $Q(x^{(N)})$  below will be used for  $Q(\frac{\mathbf{t}_o}{2})$ , where  $\mathbf{t}_o$  is defined by (2). Let all parameters  $b_k$  be not equal to negative integers. Let in (85) we choose

$$e^{\xi_n} = \frac{\prod_{i=1}^p \Gamma(a_i + n) \Gamma(a_i)^{-1}}{\prod_{i=1}^s \Gamma(b_i + n) \Gamma(b_i)^{-1}} = \frac{\prod_{i=1}^p (a_i)_n}{\prod_{i=1}^s (b_i)_n} \quad (88)$$

Then tau function (85) defines the following hypergeometric function

$${}_pF_s(a_1, \dots, a_p; b_1, \dots, b_s; x^{(N)}) := \sum_{\substack{\lambda \in \text{DP} \\ \ell(\lambda) \leq N}} 2^{-\ell(\lambda)} \frac{\prod_{k=1}^p (a_k)_\lambda}{\prod_{k=1}^s (b_k)_\lambda} \frac{Q_\lambda(x^{(N)})}{H_\lambda^*}, \quad (89)$$

which generalizes the hypergeometric function of one variable

$${}_pF_s(a_1, \dots, a_p; b_1, \dots, b_s; x^{(1)}) = \sum_{n=0}^{\infty} \frac{\prod_{k=1}^p (a_k)_n}{\prod_{k=1}^s (b_k)_n} \frac{x^n}{n!} \quad (90)$$

The function (89) was introduced in [9]. Here we introduce the  $q$ -deformed version of (89). If in (86) we choose

$$e^{\xi_n} = \frac{\prod_{i=1}^p (q^{a_i}; q)_n}{\prod_{i=1}^s (q^{b_i}; q)_n}, \quad (91)$$

tau function (86) defines the hypergeometric function

$${}_p\Phi_s(a_1, \dots, a_p; b_1, \dots, b_s; x^{(N)}) := \sum_{\substack{\lambda \in \text{DP} \\ \ell(\lambda) \leq N}} 2^{-\ell(\lambda)} \frac{\prod_{k=1}^p (q^{a_k}; q)_\lambda}{\prod_{k=1}^s (q^{b_k}; q)_\lambda} \frac{Q_\lambda(x^{(N)})}{H_\lambda^*(q)}, \quad (92)$$

which generalizes the basic hypergeometric function of one variable

$${}_pF_s(a_1, \dots, a_p; b_1, \dots, b_s; x^{(1)}) = \sum_{n=0}^{\infty} \frac{\prod_{k=1}^p (q^{a_k}; q)_n}{\prod_{k=1}^s (q^{b_k}; q)_n} \frac{x^n}{(q; q)_n} \quad (93)$$

Hypergeometric functions (89) and (92) may be also considered as multisoliton tau functions, see next subsection.

### 3.7 Soliton solutions and rational solutions

Let us recall, that in Remark 1 the set of the partitions  $\text{DP}_S$  was defined via a set of distinct non-negative integers  $S$  which includes zero.

**Theorem 1.** *Let  $\tau(\mathbf{t}_o, \xi, \mathbf{t}_\infty)$  be defined by (85), and  $\tau^{\text{sol}}(\tilde{\mathbf{t}}, \tilde{\mathbf{t}}^*)$  be defined by (72), where*

$$p_m = \frac{am + b}{cm + d}, \quad m \in S \quad (94)$$

(in particular, one can take integer momentum  $p_m = m$ ), with any  $a, b, c, d$  such that

$$\frac{ad + bc}{ad - bc} = \gamma, \quad (95)$$

is not zero or infinity, and

$$a_{i,j} = \gamma q_{i,j} \left(\frac{1}{2} \mathbf{t}_o^*\right) \quad (96)$$

Let for a given set of the numbers  $p_m$ ,  $m \in S$ , the variables  $\tilde{\mathbf{t}}, \tilde{\mathbf{t}}^*$  are related to the variables  $\xi$  as

$$\xi_m = \sum_{k=1}^{\infty} (p_m^k \tilde{t}_k - p_m^{-k} \tilde{t}_k^*) + \log m!. \quad (97)$$

Then we have

$$\tau^{\text{sol}}(\tilde{\mathbf{t}}) = \tau(\mathbf{t}_o, \xi, \mathbf{t}_\infty). \quad (98)$$

*Proof.* Let us compare (85) and (72). First replace  $\mathbf{t}_o$  with  $\tilde{\mathbf{t}}_o$  in (72). Then a typical term on the right hand side is

$$(n_1, n_2, \dots, n_k) 2^{-k} \prod_{i < j} \frac{p_{n_i} - p_{n_j}}{p_{n_i} + p_{n_j}} \prod_{i=1}^k e^{\xi(p_{n_i}, \tilde{\mathbf{t}}_o)}, \quad (99)$$

where  $0 \leq n_1 < n_2 < \dots < n_k$  and  $k$  is even. We can set  $\xi(p_k, \tilde{\mathbf{t}}_o) = \xi_k$ , choose the parameters  $p_k = k$  and the pfaffian elements to be (for  $i < j$ )

$$(i, j) = \begin{cases} \frac{2q_j(\frac{1}{2}\mathbf{t}_o)}{j!} & i = 0 \\ \frac{q_{j,i}(\frac{1}{2}\mathbf{t}_o)}{i! j!} & i > 0 \end{cases}, \quad (100)$$

so that

$$(n_1, n_2, \dots, n_k) = \begin{cases} 2 \prod_{i=1}^k \frac{1}{n_k!} Q_\lambda(\frac{1}{2}\mathbf{t}_o) & n_1 = 0 \\ \prod_{i=1}^k \frac{1}{n_k!} Q_\lambda(\frac{1}{2}\mathbf{t}_o) & n_1 > 0 \end{cases} \quad (101)$$

where  $\lambda$  is the partition into distinct parts  $(n_k, n_{k-1}, \dots, n_1)$ .

Thus the typical term may be written as

$$2^{-\ell(\lambda)} \prod_{i=1}^{\ell(\lambda)} e^{\xi_k} Q_\lambda(\frac{1}{2}\mathbf{t}_o) Q_\lambda(\frac{1}{2}\mathbf{t}_\infty), \quad (102)$$

for any partition into distinct parts. The partitions into an odd number of distinct parts come from those terms for which  $n_1 = 0$ . The extra factors of 2 in the pfaffian element in (100) and (101) are needed because in the case  $n_1 = 0$ , the length of the partition  $\ell(\lambda)$  is  $k - 1$  not  $k$ .

This establishes the connection between (85) and (72).  $\square$

The hypergeometric function (89) is an example of multi-soliton tau function of the dual BKP hierarchy, evaluated at special values of times  $\tilde{\mathbf{t}}_o$ , see (88) and (97).

**Theorem 2.** *Tau functions  $\tau(\mathbf{t}_o, \xi, \mathbf{t}_\infty)$  and  $\tau_{\text{KdV}}^{\text{sol}}(\tilde{\mathbf{t}}_o)$  are defined respectively by (85) and by (60). Let us choose  $p_m$  in (60) by*

$$p_m = \frac{am + b}{cm + d}, \quad m \in S, \quad (103)$$

where  $a, b, c, d$  are any parameters with the property

$$\frac{ad - bc}{ad + bc} = \pm 1 \quad (104)$$

(in particular, one can choose integer momentum  $p_m = m$ ,  $m \in S$ ). Let the numbers  $\xi_m$  in (85) be related to  $\eta(\mathbf{t}_o, p_m)$  in (60) by

$$\xi_m - \log m! = \eta_m := 2 \sum_{k=1}^{\infty} p_m^{2k-1} \tilde{t}_{2k-1} \quad (105)$$

Then

$$\tau_{\text{KdV}}^{\text{sol}}(\tilde{\mathbf{t}}_o) = \tau(\mathbf{t}_\infty, \xi, \mathbf{t}_\infty). \quad (106)$$

The hypergeometric function (89), where  $x_1 = x_2 = \dots = N^{-1}$  and  $N \rightarrow \infty$ , is an example of multi-soliton KdV tau function, evaluated at special values of times  $\tilde{\mathbf{t}}_o$ , see (88), (105) and Remark 6.

**Theorem 3.** *Tau functions  $\tau(\mathbf{t}_o, \xi, \mathbf{t}_o(q))$  and  $\tau_{\text{IDTL}}^{\text{sol}}(\tilde{n}, \tilde{\mathbf{t}}, \tilde{\mathbf{t}}^*)$  are defined respectively by (86) and by (65). Let  $p_m$  in (65) be chosen by*

$$p_m = \pm \frac{aq^m + b}{bq^m + a}, \quad m \in S \quad (107)$$

(in particular,  $p_m = q^m$ ,  $m \in S$ ). Let the numbers  $\xi_m$  in (86) be related to  $\eta(\mathbf{t}_o, p_m)$  in (65) by

$$\xi_m - \log \frac{(q; q)_m}{(-q; q)_m} = \eta_m := 2 \sum_{k=1}^{\infty} (p_m^k - p_m^{-k})(\tilde{t}_k + \tilde{t}_k^*) + 2\tilde{n} \log p_m \quad (108)$$

Then

$$\tau_{\text{1DTL}}^{\text{sol}}(\tilde{n}, \tilde{\mathbf{t}} + \tilde{\mathbf{t}}^*) = \tau(\mathbf{t}_o(q), \xi, \mathbf{t}_o(q)). \quad (109)$$

For the particular choice  $p_m = m$ ,  $m \in S$ , this is also NLS multi-soliton tau function.

The hypergeometric function (92), where  $x_k = q^{k-1}$ ,  $k = 1, 2, \dots$  and  $N \rightarrow \infty$ , is an example of multi-soliton 1DTL tau function evaluated at special values of times  $\tilde{\mathbf{t}} + \tilde{\mathbf{t}}^*$ , see (91), (108) and Remark 6.

*Remark 7.* In case  $S$  is a finite set, the polynomial  $\tau$ -function of type (85) (and (86)) is related to the soliton  $\tau$ -function with a finite number of solitons.

*Remark 8.* We note that the higher times  $\mathbf{t}_o$  of the BKP hierarchy we started with are integrals of motion for (solitonic)  $\tau$ -function (72) of the second BTL hierarchy. Simultaneously, the higher times  $\tilde{n}, \tilde{\mathbf{t}}, \tilde{\mathbf{t}}^*$  play the role of integrals of motion for the original BKP hierarchy. We therefore call these hierarchies dual to each other.

*Remark 9.* An  $\infty$ -soliton solution with spectral parameters lying on a lattice appeared in [12–14] in a different way and in a different context. Other links between soliton and rational solutions of the KP hierarchy were found in [15].

## 4 Discussion

An interesting problem is to study the asymptotic behaviour of hypergeometric  $\tau$ -functions. We hope to apply methods of soliton theory to conduct this study. We note that the asymptotic behaviour of infinite soliton  $\tau$ -functions, similar to those considered in the present paper, was studied in [13].

We hope to apply the series (1) to certain problems.

(1) Let us consider an integral

$$I(N, \mathbf{t}_o, \mathbf{t}_o^*) = \frac{1}{N!} \int_{\Gamma} \int_{\Gamma} \dots \int_{\Gamma} \prod_{i < j}^N \frac{(z_i - z_j)(z_i^* - z_j^*)}{(z_i + z_j)(z_i^* + z_j^*)} \prod_{k=1}^N e^{\sum_{n=1,3,\dots}^{\infty} (z_k^n t_n + z_k^{*n} t_n^*)} \mu(z_k z_k^*) dz_k dz_k^*, \quad (110)$$

where  $\Gamma$  is a integration domain in each  $(z_k, z_k^*)$  plane ( $k = 1, \dots, N$ ), and  $\mu$  is a function such that

$$\int_{\Gamma} \int_{\Gamma} \mu(z z^*) z^n dz dz^* = \int_{\Gamma} \int_{\Gamma} \mu(z z^*) z^{*n} dz dz^* = \delta_{n,0}, \quad (111)$$

and

$$\int_{\Gamma} \int_{\Gamma} \mu(z z^*) z^n z^{*m} dz dz^* = 2\delta_{n,m} e^{\xi_n}. \quad (112)$$

The series (1) (in the case that the sum ranges over partitions of length  $\ell(\lambda) \leq N$ ) yields the asymptotic expansion for the integral (110) [9]

$$I(N, \mathbf{t}_o, \mathbf{t}_o^*) = \sum_{\lambda \in \text{DP}, \ell(\lambda) \leq N} 2^{-\ell(\lambda)} e^{\sum_{i=1}^{\ell(\lambda)} \xi_{\lambda_i}} Q_{\lambda}(\frac{1}{2}\mathbf{t}_o) Q_{\lambda}(\frac{1}{2}\mathbf{t}_o^*). \quad (113)$$

The restriction  $\ell(\lambda) \leq N$  makes the difference between the r.h.s. of (113) and  $\tau(\mathbf{t}_o, \xi, \mathbf{t}_o^*)$ .

In the limit  $N \rightarrow \infty$  (which is typical for applications), the restriction  $\ell(\lambda) \leq N$  is irrelevant for the perturbation series related to (110), and therefore, this series coincides with (1). Also, in the case that at least one of the sets  $\mathbf{t}_o, \mathbf{t}_o^*$  has the form of

$$m\mathbf{t}_m = \sum_k^N (x_k^m - (-x_k)^m), \quad m\mathbf{t}_m^* = \sum_k^N (y_k^m - (-y_k)^m), \quad (114)$$

then by the bosonization formulae and Wick's Theorem we get that

$$Q_\lambda(\frac{1}{2}\mathbf{t}_o) = 0, \quad \ell(\lambda) > N \quad (115)$$

Therefore, in this case, the integral  $I(N, \mathbf{t}_o, \mathbf{t}_o^*)$  is the BKP  $\tau$ -function  $\tau(\mathbf{t}_o, \xi, \mathbf{t}_o^*)$ .

It may be interesting to apply (1) to matrix models and to statistical models where partition functions reduce to integrals (110), see, for instance, [11] for examples of integrals similar to (110).

It is interesting to compare integrals (110) with supersymmetric matrix models [33].

(2) The series (1) can be studied also in the context of random (strict) partitions.

Random strict partitions were considered in [16] and, in particular, the "shifted" measure  $Q_\lambda(x)Q_\lambda(y)$  on (strict) partitions, were considered in [16]. In this paper, the series (1), where all  $\xi_n = 0$ , and where  $\lambda_1$  does not exceed a certain given number was studied.

Let us remark that the expression

$$e^{\sum_{i=1}^{\infty} \xi_{\lambda_i}} Q_\lambda(\mathbf{t}_\infty) Q_\lambda(\mathbf{t}_\infty) = \prod_{i=1}^{\ell(\lambda)} e^{\xi_i} \left( \prod_{i=1}^k \frac{1}{\lambda_i!} \prod_{i < j}^k \frac{\lambda_i - \lambda_j}{\lambda_i + \lambda_j} \right)^2 = \left( \frac{1}{H_\lambda^*} \right)^2 e^{\sum_{i=1}^{\infty} \xi_{\lambda_i}}, \quad (116)$$

(where  $H_\lambda^*$  is known to be related to the number of shifted tableau of the shape  $\lambda$ , see [17], [6]) in the case

$$\xi_n = 0, \quad n = 0, 1, 2, \dots \quad (117)$$

may be considered as the analogue of the Plancherel measure [34], while in the case

$$e^{\xi_n} = (z)_n (1-z)_n, \quad (z)_n = \frac{\Gamma(z+n)}{\Gamma(z)}, \quad n = 0, 1, 2, \dots \quad (118)$$

as an analog of the so-called  $(z)$ -measure on random partitions (see [34]).

(3) Finally, we note that KdV soliton solutions with integer momenta was first considered in [12]. Each KdV solution of this type yields a wave operator  $\partial_t^2 - \Delta_{2n-1} - u$ , where the potential  $u = 2\partial_{t_1}^2 \tau_{\text{KdV}}^{\text{sol}}(t_1)$ , which satisfies the so-called generalized Huygens principle.

## Acknowledgements

The authors are grateful to T. Shiota for useful discussion. The work was supported in part by the Russian Foundation for Fundamental Researches (Grant No 02-02-17382), and the Program of Russian Academy of Science "Mathematical Methods in Nonlinear Dynamics". We thank Claire Gilson and Chris Athorne for the organization of the visit of one of the authors (A.O.) to the University of Glasgow, during which work on this paper was initiated.
