Abstract

A proper formulation in the perturbative renormalization group method is presented to deduce amplitude equations. The formulation makes it possible not only avoiding a serious difficulty in the previous reduction to amplitude equations by eliminating all of the secular terms but also consistent derivation of higher-order correction to amplitude equations.

PACS number:47.20.Ky

Recently a novel method based on the perturbative renormalization group (RG) theory has been developed as an asymptotic singular perturbation technique by L.Y.Chen, N.Goldenfeld and Y.Oono [1]. Their renormalization group method (RGM) removes secular or divergent terms from a perturbation series by renormalizing integral constants of lower order solutions. Although they have impressively succeeded in application to ordinary differential equations [2], a consistent formulation of the RG method does not have been established for application to partial differential equations. In fact, we have recently pointed out [7], [8] that all of secular solutions of a perturbation series does not have been eliminated yet in the previous derivation of amplitude equations from partial differential equations [2], [3].

In this paper, we present a suitable formulation of a perturbation problem in RGM in order to avoid such a difficulty and deduce some amplitude equations and their higher-order correction consistently in the framework of RGM. A crucial part of our formulation is to scale all variables except one independent variable so that the non-scaled variable is taken as a parameter of RG. Therefore, the renormalization group equations (RGE) or amplitude equations depend on the choice of scale, that is, the initial setting of a perturbation problem, of which significance is pointed out by S.Sasa [9].

(I) As the first example, we derive an amplitude equation from the following weakly nonlinear wave equation:

$$\partial_t^2 u - \partial_x^2 u + (1 + \epsilon^2 u^2) u = 0, \tag{1}$$

where ϵ is a small parameter. In order to focus our attention to a slowly-varing amplitude, let us introduce a complex amplitude A and a stretched variable ξ :

$$u = A \exp[i(kx - \omega t)] + c.c., \quad \xi = \epsilon x, \tag{2}$$

where k is a wavenumber, $\omega = \sqrt{1 + k^2}$ and c.c. denotes complex conjugate, then Eq.(1) is rewritten as

$$[LA - \epsilon(2ik\partial_{\xi} + \epsilon\partial_{\xi}^{2})A + 3\epsilon^{2}|A|^{2}A]e^{i\theta} + \epsilon^{2}A^{3}e^{3i\theta} + c.c. = 0,$$
(3)

where $L \equiv \partial_t^2 - 2i\omega\partial_t$ and $\theta = kx - \omega t$. In this formulation, t is chosen as a parameter of RG. Substituting an expansion

$$A = A_0(\xi) + \epsilon A_1 + \epsilon^2 A_2 + \epsilon^3 A_3 + \cdots,$$
(4)

into Eq.(3) and retaining only secular contribution, we have, up to order ϵ^3 ,

$$LA_{1} = 2ik\partial_{\xi}A_{0},$$

$$LA_{2} = 2ik\partial_{\xi}A_{1} + \partial_{\xi}^{2}A_{0} - 3|A_{0}|^{2}A_{0},$$

$$LA_{3} = 2ik\partial_{\xi}A_{2} + \partial_{\xi}^{2}A_{1} - 6|A_{0}|^{2}A_{1} - 3A_{0}^{2}\bar{A}_{1},$$

where \overline{A} is complex conjugate of A. Noting that secular (polynomial) solutions of $LP_j = t^j$ are given by

$$P_0 = \frac{it}{2\omega}, \quad P_1 = \frac{it^2}{4\omega} + \frac{t}{4\omega^2}, \quad P_2 = \frac{it^3}{6\omega} + \frac{t^2}{4\omega^2} - \frac{it}{4\omega^3},$$

we obtain the following secular solution up to order ϵ^3

$$A = A_0 + t \left[-\epsilon \dot{\omega} \partial_{\xi} A_0 + \epsilon^2 \frac{i}{2} (\ddot{\omega} \partial_{\xi}^2 A_0 - \frac{3}{\omega} |A_0|^2 A_0) - \epsilon^3 \frac{\dot{\omega}}{2\omega} \partial_{\xi} (\ddot{\omega} \partial_{\xi}^2 A_0 - \frac{3}{\omega} |A_0|^2 A_0)\right] + \frac{t^2}{2} (\epsilon^2 \dot{\omega}) [\dot{\omega} \partial_{\xi} A_0 - i\epsilon \partial_{\xi} (\ddot{\omega} \partial_{\xi}^2 A_0 - \frac{3}{\omega} |A_0|^2 A_0)] - \epsilon^3 \frac{t^3}{6} \dot{\omega}^3 \partial_{\xi}^3 A_0,$$

$$(5)$$

where $\dot{\omega} = d\omega/dk$ and $\ddot{\omega} = d\dot{\omega}/dk$. All of secular terms in Eq.(5) are removed by renormalizing A_0 and the renormalized amplitude A is described by RGE:

$$\partial_t A = -\epsilon \dot{\omega} \partial_\xi A + \epsilon^2 \frac{i}{2} (\ddot{\omega} \partial_\xi^2 A - \frac{3}{\omega} |A|^2 A) - \frac{\dot{\omega}}{2\omega} \partial_\xi (\ddot{\omega} \partial_\xi^2 A - \frac{3}{\omega} |A|^2 A), \tag{6}$$

$$\partial_t^2 A = \epsilon^2 \dot{\omega} [\dot{\omega} \partial_\xi A - i\epsilon \partial_\xi (\ddot{\omega} \partial_\xi^2 A - \frac{3}{\omega} |A|^2 A), \tag{7}$$

$$\partial_t^3 A = -\epsilon^3 \dot{\omega}^3 \partial_\xi^3 A,\tag{8}$$

where Eq.(6) is the nonlinear Schrödinger equation with correction up to order ϵ^3 , while Eqs.(7) and (8) are easily shown to be compatible with Eq.(6) up to order ϵ^3 . Since the above procedure continues to arbitrary order in ϵ , we can derive systematically the nonlinear Schrödinger equation with correction up to arbitrary order.

(II) Let us derive slowly-varing amplitude equations from the Swift-Hohenberg equation[4]:

$$[\partial_t + (1 + \Delta)^2 - \epsilon^2 (1 - u^2)]u = 0,$$
(9)

where $\Delta \equiv \partial_x^2 + \partial_y^2$. Introducing a complex amplitude A and stretched variables τ and η as

$$u = A \exp(ix) + c.c., \quad \tau = \epsilon^m t, \quad \eta = \epsilon^n y,$$

where m and n are positive constants, we rewrite Eq.(9) as

$$[MA + 2\epsilon^{2n}(2i\partial_x + \partial_x^2)\partial_\eta^2 A + \epsilon^{4n}\partial_\eta^4 A + \epsilon^m\partial_\tau A - \epsilon^2(1 - 3|A|^2)A]e^{ix} + \epsilon^2 A^3 e^{3ix} + c.c. = 0,$$
(10)

where $M \equiv (\partial_x^2 + 2i\partial_x)^2$ and x is a parameter of renormalization group. When we set m = 2and n = 1/2, we obtain the secular solution of Eq.(10), through the perturbative procedure similar to the example (I), as

$$A = A_{0}(\tau, \eta) + x\epsilon C_{0}(\tau, \eta) + \frac{x^{2}}{2} \left[-\frac{\epsilon^{2}}{4} B_{0} + \frac{\epsilon^{3}}{4} \left(\frac{1}{2} \partial_{\eta}^{2} B_{0} + i(\partial_{\tau} + \partial_{\eta}^{4} - 1 + 6|A_{0}|^{2}) C_{0} + 3iA_{0}^{2}\bar{C}_{0} \right] - \frac{x^{3}}{6} \frac{\epsilon^{3}}{4} \left[i\partial_{\eta}^{2} B_{0} - (\partial_{\tau} + \partial_{\eta}^{4} - 1 + 6|A_{0}|^{2}) C_{0} - 3A_{0}^{2}\bar{C}_{0} \right],$$
(11)

where \overline{C} is complex conjugate of C and

$$B_0 = -(\partial_\tau + \partial_\eta^4 - 1 + 3|A_0|^2)A_0 - 4i\partial_\eta^2 C_0.$$

Renormalizing $A_0 \to A$, $B_0 \to B$ and $C_0 \to C$ so that secular terms in Eq.(11) are removed, we get the following RGE.

$$\partial_x A = \epsilon C,\tag{12}$$

$$\partial_x^2 A = -\frac{\epsilon^2}{4}B + \frac{\epsilon^3}{4} [\frac{1}{2}\partial_\eta^2 B + i(\partial_\tau + \partial_\eta^4 - 1 + 6|A|^2)C + 3iA^2\bar{C}],$$
(13)

$$\partial_x^3 A = -\frac{\epsilon^3}{4} [i\partial_\eta^2 B - (\partial_\tau + \partial_\eta^4 - 1 + 6|A|^2)C - 3A^2\bar{C}].$$
(14)

Eliminating C from Eqs.(12) and (13), we have the Newell-Whitehead-Segel equation [5] with correction up to order ϵ^3 .

$$\partial_x^2 A = i\epsilon (1 - \frac{\epsilon}{2}\partial_\eta^2)\partial_x \partial_\eta^2 A + \frac{\epsilon^2}{4}(1 + i\partial_x - \frac{\epsilon}{2}\partial_\eta^2)(\partial_\tau + \partial_\eta^4 - 1 + 3|A|^2)A.$$

It is easy to see that Eq.(14) is compatible with Eqs.(12) and (13). If we set m = 2 and n = 1, the similar procedure yields another amplitude equation up to order ϵ^3 :

$$\partial_x^2 A = \frac{\epsilon^2}{4} (1 + i\partial_x)(\partial_\tau - 1 + 3|A|^2)A + i\epsilon^2 \partial_x \partial_\eta^2 A.$$

(III)As a final example, we derive a slow amplitude equation from the following model equation:

$$\{\partial_t [\partial_t + (k^2 + \Delta)^2 - \epsilon^2 (1 - u^2)] - \Delta\} u + (1 + \epsilon^2 u^2) u = 0,$$
(15)

The nonlinear wave equation (1) and the Swift-Hohenberg equation (9) are combined in the model equation (15) ,which may be one of the simplest equations describing the Hopf bifurcation in continuous media. Let us choose t as a parameter of RG and introduce a complex amplitude A and a stretched variable ξ in the same way as the first example (see Eq.(2)) and $\eta = \epsilon y$, then we can derive the following two-dimensional complex Ginzburg-Landau equation [6] with correction up to order ϵ^3 after following the similar procedure used in the above examples:

$$(\partial_t + \epsilon \dot{\omega} \partial_\xi) A = \frac{i\epsilon^2}{2} B - \frac{\dot{\omega}\epsilon^3}{2\omega} \partial_\xi (\ddot{\omega} \partial_\xi^2 + \frac{\dot{\omega}}{k} \partial_\eta^2 - 3|A|^2) A,$$

where

$$B = [(\ddot{\omega} - 4ik^2)\partial_{\xi}^2 + \frac{\dot{\omega}}{k}\partial_{\eta}^2 - i - 3(1-i)|A|^2]A.$$

In summary, we present a proper formulation in the perturbative renormalization group method and deduce typical amplitude equations and their higher-order correction consistently. In our formulation, we can avoid the serious difficulty appearing in the previous derivation of amplitude equations by changing the initial setting of a perturbation problem.
