Effect of a thin optical Kerr medium on a Laguerre-Gaussian beam

Weiya Zhang[∗](#page-2-0) and Mark G. Kuzyk[†](#page-2-1)

Department of Physics and Astronomy, Washington State University, Pullman, WA 99164-2814

Using a generalized Gaussian beam decomposition method we determine the propagation of a Laguerre-Gaussian (LG) beam that has passed through a thin nonlinear optical Kerr medium. The orbital angular momentum per photon of the beam is found to be conserved while the component beams change. As an illustration of applications, we propose and demonstrate a z-scan experiment using an LG_0^1 beam and a dye-doped polymer film.

Laguerre-Gaussian (LG) modes were discovered soon af-ter the invention of the laser^{[1](#page-2-2)}. A LG beam with angular mode number l and transverse radial mode number p can be written as:

$$
LG_p^l(r, \phi, z) = \left(\frac{\omega_0}{\omega(z)}\right) \left(\frac{\sqrt{2}r}{\omega(z)}\right)^{|l|} L_p^{|l|} \left(\frac{2r^2}{\omega^2(z)}\right)
$$

$$
\times \exp\left(\frac{-r^2}{\omega^2(z)}\right) \exp\left(-i\frac{kr^2z}{2(z^2+z_r^2)}\right)
$$

$$
\times \exp\left(i\left(2p+|l|+1\right)\tan^{-1}\left(\frac{z}{z_r}\right)\right)
$$

$$
\times \exp(-il\phi) \exp(-ikz), \qquad (1)
$$

where ω_0 is the beam waist radius, $z_r = k\omega_0^2/2$ is the Rayleigh length, $\omega(z) = \omega_0 (1 + z^2/z_0^2)^{\frac{1}{2}}$ is the beam radius at z, and L_p^l is an associated Laguerre polynomial. For a given LG beam mode, z_r (or ω_0) alone is sufficient to characterize the relative amplitude and phase of the electric field of the beam. When multiple beams are involved, it is often necessary to specify the waist locations of each beam. For convenience we use the notation $C \cdot LG_p^l(r, \phi, z-z_w; z_r)$ to describe a LG beam unambiguously, where z_w is the waist location on the z axis and C is a complex constant that gives the amplitude and the initial phase.

The fundamental Gaussian beam LG_0^0 has been the most commonly studied LG mode in both theory and experiment. However recently higher order LG beams, especially those with higher angular mode number l , are attracting more attention. When $l \geq 1$, the LG beam possesses well defined orbital angular momentum of $l\hbar$ per photon[2](#page-2-3) , zero on-axis intensity due to the phase singularity, and helical phase fronts. These properties make high-order LG beams useful in many applications such as optical manipulation of microscopic particles^{[3](#page-2-4)}, quan-tum information processing^{[4](#page-2-5)[,5](#page-2-6)}, orbital angular momen-tum sorting^{[6](#page-2-7)} and imaging^{[7](#page-2-8)}, nonlinear wave mixing^{[8](#page-2-9)}, op-tical vortices^{[9](#page-2-10)} and vortex solitons^{[10](#page-2-11)}, scattering^{[11](#page-2-12)}, and interference^{[12](#page-2-13)}. In the present work, we develop a theory for the propagation of an LG beam after it passes through a thin nonlinear optical Kerr medium. The results of our calculation can be used for z-scan measurements using LG_0^1 beam and optical limiting geometries.

The index of refraction of an optical Kerr medium depends on the intensity I of the incident beam and the nonlinear refractive index n_2 ,

$$
n = n_0 + n_2 I,\tag{2}
$$

where n_0 is the linear refractive index. Consider a nonlinear Kerr-type sample that is placed at the position $z = z_s$

in a LG beam $E(r, \phi, z) = E_0 \cdot LG_{p_0}^{l_0}(r, \phi, z; z_r)$. Assume the sample is "thin" such that the change of the diameter of the beam due to either linear diffraction or nonlinear refraction can be neglected within the sample. Such two requirements are satisfied if $d \ll z_r$ and $d \ll z_r/\Delta\Phi$, respectively, where d is the sample thickness, and $\Delta\Phi$ is the nonlinear phase distortion^{[14](#page-2-14)}. The electric field E' at the exit surface of the sample can be expressed $as^{13,14}$ $as^{13,14}$ $as^{13,14}$ $as^{13,14}$

$$
E'(r, \phi, z_s) = E(r, \phi, z_s) e^{-\frac{\alpha d}{2}} e^{-i\Delta \Phi(r, \phi, z_s)}, \quad (3)
$$

where α is the linear absorption coefficient, and

$$
\Delta\Phi(r,\phi,z) = \frac{\Delta\Phi_0}{1+z^2/z_r^2} \left(\frac{2r^2}{\omega^2(z)}\right)^{|l_0|} \times \left(L_{p_0}^{|l_0|} \left(\frac{2r^2}{\omega^2(z)}\right)\right)^2 \exp\left(\frac{-2r^2}{\omega^2(z)}\right), \tag{4}
$$

where

$$
\Delta\Phi_0 = \frac{\pi}{\lambda} c\epsilon_0 n_0 n_2 |E_0|^2 \frac{1 - e^{-\alpha d}}{\alpha} \tag{5}
$$

is a constant proportional to the maximum nonlinear phase change $\Delta\Phi_{max}(z_s)$ in the sample at the focus $(z_s = 0)$. When the incident beam is a LG_0^0 beam, $\Delta \Phi_0 = \Delta \Phi_{max}(z_s = 0).$

We generalize the so-called "Gaussian decomposition" method^{[15](#page-2-16)} to analyze the propagation of a beam that traverses a nonlinear sample. The exponential in Eq. [\(3\)](#page-0-0) can be expanded in a Taylor series as

$$
e^{-i\Delta\Phi(r,\phi,z_s)} = \sum_{m=0}^{\infty} \frac{\left(-i\Delta\Phi(r,\phi,z_s)\right)^m}{m!}.\tag{6}
$$

The complex electric field of the incident beam after it passes through the sample can be written as a summation of the electric fields of a series of LG beams of different modes as

$$
E'(r, \phi, z) = \sum_{m=0}^{\infty} \sum_{p=0}^{p_m} C_{p,m} LG_p^{|l_0|}(r, \phi, z - z_{wm}; z_{rm}),
$$
\n(7)

where z_{wm} and z_{rm} are the waist location and the Rayleigh length, respectively, of the corresponding beam mode and $C_{p,m}$ is the amplitude and phase of the component beam. These parameters are determined by letting $z = z_s$ in Eq. [\(7\)](#page-0-1) and making use of Eqs. [\(3\)](#page-0-0) and [\(6\)](#page-0-2).

$$
z_{\omega m} = z_r \frac{4m(m+1) Z}{Z^2 + (2m+1)^2},
$$

$$
z_{rm} = z_r \frac{(2m+1) (Z^2 + 1)}{Z^2 + (2m+1)^2},
$$

and $C_{p,m} = D_{p,m} \cdot F_{p,m}$ where Z is defined as $Z = z_s/z_r$, and

$$
F_{p,m} = E_0 e^{-\alpha d/2} \frac{(-i\Delta\Phi_0)^m}{m! (2m+1)} \sqrt{\frac{(2m+1)^2 + Z^2}{(1+Z^2)^{2m+1}}} \times \exp\left(-ikz_r \frac{4m(m+1)Z}{Z^2 + (2m+1)^2}\right) \times \exp\left(i (2p_0 + |l_0| + 1) \tan^{-1}(Z)\right) \times \exp\left(-i (2p + |l_0| + 1) \tan^{-1}\left(\frac{Z}{2m+1}\right)\right),
$$

and p_m and $D_{p,m}$ are determined through

$$
\sum_{p=0}^{p_m} D_{p,m} \cdot L_p^{|l_0|}(x) = \frac{x^{m|l_0|} \left(L_{p_0}^{|l_0|} \left(\frac{x}{2m+1} \right) \right)^{2m+1}}{(2m+1)^{\frac{2m+1}{2}|l_0|}},
$$

where x is an arbitrary real variable. Our theoretical results are embodied in Eq. [\(7\)](#page-0-1).

It is worth noting that all the component LG beams have the same angular mode number l_0 as that of the incident beam, which reflects the conservation of the photon's orbital angular momentum. Therefore the effect of the Kerr material on the incident LG beam is to generate LG beams of different radial modes. These results are important in applications that leverage mode sensitivity.

The expression in Eq. [\(7\)](#page-0-1) is especially useful when the nonlinear phase distortion is small enough so that only a few terms in the summation are needed to make a good approximation. To illustrate, assume that the incident beam is a LG_0^1 beam and the maximum nonlinear phase distortion in the sample at position Z is

$$
|\Delta\Phi_{max}\left(Z\right)| = \frac{|\Delta\Phi_0|}{e \cdot (1+Z^2)} << 1.
$$
 (8)

It is sufficient to keep the first two terms in the Eq. [\(6\)](#page-0-2) and neglect the higher order terms, yielding

$$
E'(r, \phi, z) \approx F_{0,0} LG_0^1(r, \phi, z; z_r)
$$

+
$$
\frac{2}{3\sqrt{3}} F_{0,1} LG_0^1(r, \phi, z - z_{w1}; z_{r1})
$$

-
$$
\frac{1}{3\sqrt{3}} F_{1,1} LG_1^1(r, \phi, z - z_{w1}; z_{r1}).
$$
 (9)

This outgoing electric field includes the generated LG_0^1 and LG_1^1 beam.

It is interesting to calculate the on-axis normalized Zscan transmittance 13,14 13,14 13,14 13,14

$$
T(Z, \Delta \Phi_0) = \frac{|E'(r \to 0, \phi, z \to \infty)|^2}{|E'(r \to 0, \phi, z \to \infty)|_{\Delta \Phi_0 = 0}|^2},
$$
 (10)

which characterizes the on axis light power transmitted though a small aperture placed in the far field. Applying Eq. (9) we find

$$
T(Z, \Delta \Phi_0) = 1 + \frac{8Z (27 + 10Z^2 - Z^4)}{(1 + Z^2) (9 + Z^2)^3} \Delta \Phi_0
$$

+
$$
\frac{16}{(9 + Z^2)^3} \Delta \Phi_0^2.
$$
 (11)

The last term can be dropped if $|\Delta \Phi_0| << 1$.

The same procedures can be applied to LG beams of other modes. As a special case, when the incident beam is LG_0^0 , we get the same result as in Ref. [14](#page-2-14), i.e.

$$
T(Z, \Delta \Phi_0) = 1 + \frac{4Z}{(1 + Z^2)(9 + Z^2)} \Delta \Phi_0
$$
 (12)

when $|\Delta \Phi_0| << 1$.

Result [\(12\)](#page-1-1) was first reported as the theory supporting the Z-scan technique, a highly sensitive technique to measure the optical nonlinearities using a LG_0^0 beam^{[14](#page-2-14)}. In a Z-scan, one measures the trace of the normalized transmittance T as a function of the nonlinear sample position z, from which $\Delta\Phi_0$ is determined by fitting Eq. [\(12\)](#page-1-1) or more practically, through the relation $\Delta T_{p-v} = 0.406 |\Delta \Phi_0|$ (derived from Eq. [\(12\)](#page-1-1)), where ΔT_{p-v} is the difference between the peak (maximum) and the valley (minimum) of the trace (e.g., the dotted curve in Figure [2\)](#page-2-17). $\Delta \Phi_0$ then gives n_2 through Eq. [\(5\)](#page-0-3).

Similarly, Eq. (11) shows the relationship between T and $\Delta\Phi_0$, suggesting that it is possible to do a Z-scan experiment using the LG_0^1 beam to measure the nonlinearity of a thin samples. We demonstrate this on a dispersered-1 doped poly(methyl methacrylate) (DR1/PMMA) thin sample 16 . The experiment also tests the validity of our theory.

FIG. 1: Schematic diagram of the Z-scan experiment using a LG_0^1 beam. M: computer generated phase mask, L: lens, S: sample, A: aperture, and D: detector.

Figure [1](#page-1-3) shows a schematic diagram of the setup. A LG_0^0 beam of 647 nm wavelength from a krypton laser is converted into a LG_0^1 beam by a computer generated binary phase mask^{[17](#page-2-19)}. The LG_0^1 beam is then focused by a lens to the desired Rayleigh length (2.4 cm). The power of the incident beam is 65 μ W. A 1.4 mm-thick 2% w/w DR1/PMMA sample is placed near the beam waist. The nonlinearity of DR1/PMMA is due to photo-induced trans-cis-trans isomerization of DR1 molecules followed by reorientation in the direction perpendicular to the polarization of the incident laser beam. It can be treated as an optical Kerr effect when the intensity is low and the exposure time is short enough to avoid saturation of the refractive index change. We use a shutter (not shown) to control the total exposure time (3 seconds). A small aperture is placed on axis of the beam in the far field. The power passed through the aperture is recorded by a detector as a function of sample position z as well as the exposure time t. The normalized transmittance is obtained by dividing the power recorded by the detector at time $t = 3$ s by that at time $t = 0$ s. A fresh sample spot

is used for each exposure to avoid history effects. Nonlinear absorption is determined to be negligible with an open aperture Z-scan. The "thin" sample approximation is satisfied under the above experimental conditions.

FIG. 2: Experimental (circles) and theoretical (solid curve) results of the Z-scan of a 1.4mm-thick 2% DR1/PMMA sample using a LG_0^1 beam. Also shown are a LG_0^0 Z-scan trace (dotted curve) and a dashed line indicating the level of $T = 1$.

Figure [2](#page-2-17) shows the results. The circles are the experimental data. The solid curve is the best fit using Eq. [\(11\)](#page-1-2) with $\Delta\Phi_0$ as the parameter. The dotted curve is the best fit using Eq. [\(12\)](#page-1-1), included as a LG_0^0 Z-scan trace for comparison. The dashed line is to indicate the line where $T = 1$.

The shape of the Z-scan curve using the LG_0^1 beam differs from the traditional one using the LG_0^0 beam in that the former has an extra peak and valley (indicated in the figure by the arrows). The extra valley brings down the tail of the major peak below $T = 1$ and the extra peak brings up the tail of the major valley beyond $T = 1$. The experimental data clearly shows these features and fits

our theory well. On the other hand, the tails in the LG_0^0 Z-scan trace never cross the $T = 1$ line and do not fit the data. Thus our theory provides the only good theory, supporting its validity. The appearance of the additional structure of our theory is a consequence of the LG_1^1 component beam in Eq. [\(9\)](#page-1-0). Although the amplitude of these features is much smaller than the major ones, it has significance in other applications such as optical limiting, which will be discussed in a future publication.

Just as the traditional LG_0^0 Z-scan, the LG_0^1 Z-scan provides sensitive measurements of optical nonlinearities. The value of $\Delta\Phi_0$ is fitted to be -1.1 (or $\Delta\Phi_{max}(Z=$ 0) = −0.4) using the data in Figure [2.](#page-2-17) With this we calculate $n_2 \approx -1.3 \times 10^{-4} \text{ cm}^2/\text{W}$, which is consistent with the value measured using the traditional LG_0^0 Zscan. Besides using the fitting method, we can also estimate $\Delta \Phi_{max}(Z=0)$ using the difference between the major peak and valley, $\Delta T_{p-v} = 0.789 \vert \Delta \Phi_{max}(Z=0) \vert$. An important difference between the two Z-scan measurements is that in the LG_0^1 Z-scan experiment the detector is placed at the beam center where the intensity is the weakest due to the screw phase dislocation while in the LG_0^0 Z-scan experiment the center intensity is the strongest. As a result the former shows a much bigger deviation from the normal value if any phase or intensity distortion that destroys the symmetry of the beam profile is present. This suggests that the LG_0^1 Z-scan experiment is more sensitive to changes of the n_2 of the sample.

In conclusion, we have calculated the propagation of a Laguerre-Gaussian beam after it passes through a thin nonlinear optical Kerr medium. Applications, such as the Z-scan experiment using a LG_0^1 beam described here, has advantages over traditional measurements using a LG_0^0 beam. These results can be applied to many other thin film applications such as optical limiting and nonlinear beam interactions.
