## <span id="page-0-0"></span>Quantum mechanics with time-dependent parameters

G. SARDANASHVILY<sup>1</sup>

Department of Theoretical Physics, Moscow State University, 117234 Moscow, Russia

Abstract. Composite bundles  $Q \to \Sigma \to \mathbf{R}$ , where  $\Sigma \to \mathbf{R}$  is the parameter bundle, provide the adequate mathematical description of classical mechanics with time-dependent parameters. We show that the Berry's phase phenomenon is described in terms of connections on composite Hilbert space bundles.

## I.

Smooth fiber bundles  $Q \to \mathbf{R}$  over a time axis **R** provide the adequate formulation of classical time-dependent mechanics treated as a particular field theory[[1](#page-6-0), [2\]](#page-6-0). Let us consider a mechanical system depending on time-dependent parameters. These parameters can be seen as sections of some smooth fiber bundle  $\Sigma \to \mathbf{R}$ . Then the configuration space of a mechanical system with time-dependent parameters can be seen as the composite fiber bundle

$$
Q \to \Sigma \to \mathbf{R}.\tag{1}
$$

In classical mechanics  $Q \to \Sigma$  is a smooth finite-dimensional fiber bundle. In quantum mechanics $Q \to \Sigma$  is a C<sup>\*</sup>-algebra fiber bundle or a Hilbert space fiber bundle [[3\]](#page-6-0).

The following two facts make the composite fiber bundle (1) useful for our purpose.

(i) Given a section h of a parameter bundle  $\Sigma \to \mathbf{R}$ , the pull-back bundle  $h^*Q$  over **R** describes a mechanical system under the fixed parameter functions  $h(t)$ .

(ii) Given a connection  $A_{\Sigma}$  on the fiber bundle  $Q \to \Sigma$ , the pull-back connection  $h^* A_{\Sigma}$ on the pull-back bundle  $h^*Q \to \mathbf{R}$  depends in a certain way on the parameter functions  $h(t)$ , and characterizes the dynamics of a mechanical system with time-dependent parameters.

This work is devoted to quantum mechanics with classical parameters where connections on composite Hilbert space bundles play the role of Berry connections.

### II.

Recall that by a smooth composite bundle is meant the composition of fiber bundles

$$
Y \to \Sigma \to X,\tag{2}
$$

<sup>1</sup>Electronic mail: sard@grav.phys.msu.su; sard@campus.unicam.it

<span id="page-1-0"></span>where  $\pi_{Y\Sigma}: Y \to \Sigma$  and  $\pi_{\Sigma X}: \Sigma \to X$  are smooth fiber bundles [\[3](#page-6-0), [4\]](#page-6-0). It is provided with an atlas of fibered coordinates  $(x^{\lambda}, \sigma^m, y^i)$ , where  $(x^{\mu}, \sigma^m)$  are fibered coordinates on the fiber bundle  $\Sigma \to X$  and the transition functions  $\sigma^m \to \sigma'^m(x^{\lambda}, \sigma^k)$  are independent of the fiber coordinates  $y^i$ .

*Proposition 1:* Given a composite fiber bundle  $(2)$ , let h be a global section of the fiber bundle  $\Sigma \to X$ . Then the restriction

$$
Y_h = h^*Y \tag{3}
$$

of the fiber bundle  $Y \to \Sigma$  to  $h(X) \subset \Sigma$  is a subbundle  $i_h: Y_h \hookrightarrow Y$  of the fiber bundle  $Y \to X$ .

Let us consider a connection

$$
A_{\Sigma} = dx^{\lambda} \otimes (\partial_{\lambda} + A_{\lambda}^{i} \partial_{i}) + d\sigma^{m} \otimes (\partial_{m} + A_{m}^{i} \partial_{i}) : Y \to J_{\Sigma}^{1} Y
$$
\n<sup>(4)</sup>

on the fiber bundle  $Y \to \Sigma$ . Given a section h the fiber bundle  $\Sigma \to X$ , the connection  $A_{\Sigma}$ (4) induces the pull-back connection

$$
A_h = i_h^* A_\Sigma = dx^\lambda \otimes [\partial_\lambda + ((A_m^i \circ h)\partial_\lambda h^m + (A \circ h)_\lambda^i)\partial_i]
$$
(5)

on the pull-back bundle  $Y_h$  (3).

Note that, in quantum theory, one follows the notion of a connection phrased in algebraic terms as a connection on modules in comparison with the pure geometric one in classical theory. Here, we restrict our consideration to connecions on modules over the ring  $C^{\infty}(X)$ of smooth real functions on a manifold  $X$  [[3, 5\]](#page-6-0).

Definition 2: A connection on a  $C^{\infty}(X)$ -module S assigns to each vector field  $\tau$  on a manifold X an S-valued first order differential operator  $\nabla_{\tau} \in \text{Diff}_1(\mathcal{S}, \mathcal{S})$  on S which obeys the Leibniz rule

$$
\nabla_{\tau}(fs) = (\tau \rfloor df)s + f \nabla_{\tau} s, \quad f \in C^{\infty}(X), \quad s \in \mathcal{S}.
$$
 (6)

If S is a module of global sections of a smooth vector bundle  $Y \to X$  over a manifold X, Definition 2 is equivalent to the familiar geometric definition of a connection on  $Y \to X$ .

#### III.

Let us consider a quantum mechanical systems depending on a finite number of real classical parameters given by sections of a smooth parameter bundle  $\Sigma \to \mathbf{R}$ . For the sake of simplicity, we fix a trivialization  $\Sigma = \mathbf{R} \times Z$ , coordinated by  $(t, \sigma^m)$ . Although it may happen that the parameter bundle  $\Sigma \to \mathbf{R}$  has no preferable trivialization, e.g., if one of parameters is a velocity of a reference frame.

Recall that, in the framework of algebraic quantum theory, a quantum system is characterized by a  $C^*$ -algebra A and a positive (hence, continuous) form  $\phi$  on A which defines the representation  $\pi_{\phi}$  of A in a Hilbert space  $E_{\phi}$  with a cyclic vector  $\xi_{\phi}$  such that

$$
\phi(a) = \langle \pi_{\phi}(a)\xi_{\phi}|\xi_{\phi}\rangle, \qquad \forall a \in A.
$$

One says that  $\phi(a)$  is a mean value of the operator a in the state  $\xi_{\phi}$ .

It should be emphasized that, in quantum mechanics, a time also plays the role of a classical parameter. Indeed, all relations between operators in quantum mechanics are simultaneous, while a computation of a mean value of an operator in a quantum state does not imply an integration over a time. It follows that, at each moment, we have a quantum system, but these quantum systems are different at different instants. Though they may be isomorphic to each other. This characteristic is extended to other classical parameters. Namely, we assign a C<sup>\*</sup>-algebra  $A_{\sigma}$  to each point  $\sigma \in \Sigma$  of the parameter bundle  $\Sigma$ , and treat  $A_{\sigma}$  as a quantum system under fixed values  $(t, \sigma^m)$  of the parameters.

Remark 1: Let us emphasize that one should distinguish classical parameters from coordinates which a wave function can depend on. Let  $\{A_q\}$  be a set of  $C^*$ -algebras parameterized by points of a locally compact topological space Q. Let all  $C^*$ -algebras  $A_q$  are isomorphic to each other and to some  $C^*$ -algebra A. We consider a locally trivial topological fiber bundle  $P \to Q$  whose typical fiber is the C<sup>\*</sup>-algebra A, i.e., transition functions of this fiber bundle provide automorphisms of A. The set  $P(Q)$  of continuous sections of this fiber bundle is a \*-algebra with respect to fiberwise operations. Let us consider a subalgebra  $A(Q) \subset P(Q)$ which consists of sections  $\alpha$  of  $P \to Q$  such that the real function  $||\alpha(q)||$  vanishes at infinity of Q. For  $\alpha \in A(Q)$ , put

$$
||\alpha|| = \sup_{q \in Q} ||\alpha(q)|| < \infty.
$$

With this norm,  $A(Q)$  is a  $C^*$ -algebra [\[6\]](#page-6-0). One can consider a quantum system characterized by this  $C^*$ -algebra. In this case, elements of the set  $Q$  are not classical parameters as follows. Given an element  $q \in Q$ , the assignment

$$
A(Q) \ni \alpha \mapsto \alpha(q) \in A \tag{7}
$$

is a  $C^*$ -algebra epimorphism. Let  $\pi$  be a representation of A. Then the assignment (7) yields a representation  $\rho(\pi, q)$  of the C<sup>\*</sup>-algebra  $A(Q)$ . If  $\pi$  is an irreducible representation of the C<sup>\*</sup>-algebra A, then  $\rho(\pi, q)$  is an irreducible representation of  $A(Q)$ . Moreover, the irreducible representations  $\rho(\pi, q)$  and  $\rho(\pi, q')$  of  $A(Q)$  are not equivalent [\[6](#page-6-0)]. Therefore there is one-to-one correspondence (but not a homeomorphism) between the spectrum  $A(Q)$  of the

<span id="page-3-0"></span> $C^*$ -algebra  $A(Q)$  and the product  $Q \times \widehat{A}$  of Q and the spectrum  $\widehat{A}$  of the  $C^*$ -algebra A. It follows that one can find representations of the  $C^*$ -algebra  $A(Q)$  among direct integrals of representations of A with respect to some measure on  $Q$ . Let  $\mu$  be a positive measure of total mass 1 on the locally compact space  $Q$  , and let  $\phi$  be a positive form on A. Then the function  $q \mapsto \phi(\alpha(q))$ ,  $\forall \alpha \in A(Q)$ , is a  $\mu$ -measurable, while the integral

$$
\phi(\alpha) = \int \phi(\alpha(q))\mu(q)
$$

provides a positive form on the  $C^*$ -algebra  $A(Q)$ . Roughly speaking, a computation of a mean value of an operator  $\alpha \in A(Q)$  implies an integration with respect to some measure on Q in general. This is not the case of quantum systems depending on classical parameters  $q \in Q$ .

We simplify our consideration in order to single out the manifested Berry's phase phenomenon. Let us assume that all algebras  $C^*$ -algebras  $A_{\sigma}$ ,  $\sigma \in \Sigma$ , are isomorphic to the von Neumann algebra  $B(E)$  of bounded operators in some Hilbert space E, and consider a locally trivial Hilbert space bundle  $\Pi \to \Sigma$  with the typical fiber E and smooth transition functions[[7\]](#page-6-0). Smooth sections of  $\Pi \to \Sigma$  constitute a module  $\Pi(\Sigma)$  over the ring  $C^{\infty}(\Sigma)$  of real functions on Σ. In accordance with Definition [2](#page-1-0), a connection  $\widetilde{\nabla}$  on  $\Pi(\Sigma)$  assigns to each vector field  $\tau$  on  $\Sigma$  a first order differential operator

$$
\nabla_{\tau} \in \text{Diff}_1(\Pi(\Sigma), \Pi(\Sigma)) \tag{8}
$$

which obeys the Leibniz rule

$$
\widetilde{\nabla}_{\tau}(fs) = (\tau \rfloor df)s + f \widetilde{\nabla}_{\tau} s, \qquad s \in \Pi(\Sigma), \qquad f \in C^{\infty}(\Sigma).
$$

Let  $\tau$  be a vector field on  $\Sigma$  such that  $dt|\tau=1$ . Given a trivialization chart of the Hilbert space bundle  $\Pi \to \Sigma$ , the operator  $\nabla_{\tau}$  (8) reads

$$
\widetilde{\nabla}_{\tau}(s) = (\partial_t - i\mathcal{H}(t, \sigma^i))s + \tau^m(\partial_m - i\widehat{A}_m(t, \sigma^i))s,
$$
\n(9)

where  $\mathcal{H}(t, \sigma^i)$ ,  $\widehat{A}_m(t, \sigma^i)$  for each  $\sigma \in \Sigma$  are bounded self-adjoint operators in the Hilbert space  $E$ .

Let us consider the composite fiber bundle  $\Pi \to \Sigma \to \mathbf{R}$ . Similarly to the case of smooth composite fiber bundles (see Proposition [1\)](#page-1-0), every section  $h(t)$  of the parameter bundle  $\Sigma \to \mathbf{R}$  defines the subbundle  $\Pi_h = h^* \Pi \to \mathbf{R}$  of the composite fiber bundle  $\Pi \to \mathbf{R}$  whose typical fiber is the Hilbert space E. Accordingly, the connection  $\widetilde{\nabla}$  (9) on the  $C^{\infty}(\Sigma)$ -module Π(Σ) defines the pull-back connection

$$
\nabla_h(\psi) = [\partial_t - i(\hat{A}_m(t, h^i(t))\partial_t h^m + \mathcal{H}(t, h^i(t))] \psi \tag{10}
$$

<span id="page-4-0"></span>on the  $C^{\infty}(\mathbf{R})$ -module  $\Pi_h(\mathbf{R})$  of sections  $\psi$  of the Hilbert space bundle  $\Pi_h \to \mathbf{R}$ .

As in the case of smooth fiber bundles, we say that a section  $\psi$  of the fiber bundle  $\Pi_h \to \mathbf{R}$ is an integral section of the connection [\(10\)](#page-3-0) if

$$
\nabla_h(\psi) = [\partial_t - i(\hat{A}_m(t, h^i(t))\partial_t h^m + \mathcal{H}(t, h^i(t))] \psi = 0.
$$
\n(11)

One can think of the equation  $(11)$  as being the Shrödinger equation for a quantum system depending on the parameter function  $h(t)$ . Its solutions take the form

$$
G_t = T \exp\left[i\int_0^t (\widehat{A}_m \partial_{t'} h^m + \mathcal{H}) dt'\right],\tag{12}
$$

where  $G_t$  is the time-ordered exponent. The term  $i\hat{A}_m(t, h^i(t))\partial_t h^m$  in the Shrödinger equation (11) is responsible for the Berry's phase phenomenon, while  $\mathcal H$  is treated as an ordinary Hamiltonian of a quantum system.

To show the Berry's phase phenomenon clearly, we simplify again the system under consideration. Given a trivialization of the fiber bundle  $\Pi \to \mathbf{R}$  and the above mentioned trivialization  $\Sigma = \mathbf{R} \times Z$  of the parameter bundle  $\Sigma$ , let us suppose that the components  $A_m$  of the connection  $\nabla(9)$  $\nabla(9)$  $\nabla(9)$  are independent of t and that the operators  $\mathcal{H}(\sigma)$  commute with the operators  $A_m(\sigma)$  at all points of the curve  $h(t) \subset \Sigma$ . Then the operator  $G_t$  (12) takes the form

$$
G_t = T \exp\left[i \int\limits_{h([0,t])} \hat{A}_m(\sigma^i) d\sigma^m\right] \cdot T \exp\left[i \int\limits_0^t \mathcal{H}(t') dt'\right].
$$
 (13)

One can think of the first factor in the right-hand side of the expression (13) as being the operator of a parallel transport along the curve  $h([0, t]) \subset Z$  with respect to the pull-back connection

$$
\nabla = i^* \widetilde{\nabla} = \partial_m - i \widehat{A}_m(t, \sigma^i)
$$
\n(14)

on the fiber bundle  $\Pi \rightarrow Z$ , defined by the imbedding

$$
i: Z \hookrightarrow \{0\} \times Z \subset \Sigma.
$$

Note that, since operators  $A_m$  are independent of time, one can utilize any imbedding of Z to  $\{t\} \times Z$ .

Moreover, the connection  $\nabla$  (14), called the Berry connection, can be seen as a connection on some principal fiber bundle  $P \to Z$  for the group  $U(E)$  of unitary operators in the Hilbert space E. Let the curve  $h([0, t])$  be closed, while the holonomy group of the connection  $\nabla$  at the point  $h(t) = h(0)$  is not trivial. Then the unitary operator

$$
T \exp\left[i \int\limits_{h([0,t])} \widehat{A}_m(\sigma^i) d\sigma^m\right]
$$
 (15)

is not the identity. For example, if

$$
i\hat{A}_m(\sigma^i) = iA_m(\sigma^i) \text{Id}_E
$$
\n(16)

is a  $U(1)$ -principal connection on Z, then the operator [\(15\)](#page-4-0) is the well-known Berry phase factor

$$
\exp\left[i \int\limits_{h([0,t])} A_m(\sigma^i) d\sigma^m\right].
$$

If (16) is a curvature-free connection, Berry's phase is exactly the Aharonov–Bohm effect on the parameter space Z.

The following variant of the Berry's phase phenomenon leads us to a principal bundle for familiar finite-dimensional Lie groups. Let  $E$  be a separable Hilbert space which is the Hilbert sum of *n*-dimensional eigenspaces of the Hamiltonian  $\mathcal{H}(\sigma)$ , i.e.,

$$
E = \bigoplus_{k=1}^{\infty} E_k, \qquad E_k = P_k(E),
$$

where  $P_k$  are the projection operators, i.e.,

$$
H(\sigma) \circ P_k = \lambda_k(\sigma) P_k
$$

(in the spirit of the adiabatic hypothesis). Let the operators  $A_m(z)$  be time-independent and preserve the eigenspaces  $E_k$  of the Hamiltonian  $\mathcal{H}$ , i.e.,

$$
\widehat{A}_m(z) = \sum_k \widehat{A}_m^k(z) \circ P_k,\tag{17}
$$

where  $\hat{A}_m^k(z)$ ,  $z \in Z$ , are self-adjoint operators in  $E_k$ . It follows that  $\hat{A}_m(\sigma)$  commute with  $\mathcal{H}(\sigma)$  at all points of the parameter bundle  $\Sigma \to \mathbf{R}$ . Then, restricted to each subspace  $E_k$ , the parallel transport operator [\(15\)](#page-4-0) is a unitary operator in  $E_k$ . In this case, the Berry connection [\(14](#page-4-0)) on the  $U(E)$ -principal bundle  $P \to Z$  can be seen as a composite connection on the composite bundle

$$
P \to P/U(n) \to Z,
$$

which is defined by some principal connection on the  $U(n)$ -principal bundle  $P \to P/U(n)$  and the trivial connection on the fiber bundle  $P/U(n) \to Z$ . The typical fiber of  $P/U(n) \to Z$  is exactly the classifying space  $B(U(n))$  for  $U(n)$ -principal bundles. Moreover, one can consider the parallel transport along a curve in the bundle  $P/U(n)$ . In this case, a state vector  $\psi(t)$ acquires a geometric phase factor in addition to the dynamical phase factor. In particular, if  $\Sigma = \mathbf{R}$  (i.e., classical parameters are absent and Berry's phase has only the geometric origin) we come to the case of a Berry connection on the  $U(n)$ -principal bundle on the classifying space $B(U(n))$  [\[8\]](#page-6-0). If  $n = 1$ , this is the variant of Berry's geometric phase of Ref. [[9\]](#page-6-0).
